Two-Sided Matching via Balanced Exchange

Umut Mert Dur† M. Utku Ünver ‡

This Draft: November 2017

Abstract

We introduce a new matching model to mimic two-sided exchange programs such as tuition and worker exchanges, in which export-import balances are required for longevity of programs. These exchanges use decentralized markets, making it difficult to achieve this goal. We introduce the two-sided top-trading-cycles, the unique mechanism that is balanced-efficient, worker-strategy-proof, acceptable, individually rational, and respecting priority bylaws regarding worker eligibility. Moreover, it encourages exchange, because full participation is the dominant strategy for firms. We extend it to dynamic settings permitting tolerable yearly imbalances and demonstrate that its regular and tolerable versions perform considerably better than models of current practice.

1 Introduction

We introduce and model a new class of two-sided matching markets without explicit transfers, in which there is an additional fundamental constraint.\(^1\) The eventual market outcome is linked to an initial status-quo matching, which may give participants certain rights that constrain how future activity can play out. Since market outcome is typically different from the status-quo, such activities loosely resemble an *exchange* in which one side of the agents are changing or acquiring new partners besides the fundamental two-sided structure matching one side (e.g., firms/colleges) with the other (e.g., workers/students). In such markets, a fundamental *balancedness* condition needs to be sustained with respect to the status-quo matching. The motivation for such a balancedness constraint can be different depending on the features of the market. Two contrasting examples are in labor markets and higher education markets, where workers and colleges provide services to be compensated, respectively. In *worker exchange*, a worker needs to be replaced with a new one at her home firm so that this firm can function properly, and thus, the market needs to clear in a balanced manner. In *student exchange*, the college that is matched with an “exchange” student should be able to send out a student as well so that its education costs do not increase, and thus, the market needs to clear in a balanced manner. There are several prominent examples of such exchanges, such as national and international teacher-exchange programs, clinical-exchange programs for medical doctors, worker-exchange programs within or across firms, and student-exchange programs among colleges. This balancedness constraint induces preferences for firms/colleges not only over whom they get matched with (i.e., *import*), but also over whom they send out (i.e., *export*). The most basic kind of such preferences requires the firm/college to have a preference for balanced matchings, i.e., for import and export numbers to be equal. We analyze our model over two explicit market applications: (permanent) tuition exchange and temporary worker exchange.\(^2\)

In *tuition exchange*, the two sides are colleges and students. Each student (who is a dependent of a faculty member at a college) can attend another institution for free, if admitted as part of a tuition-exchange program. (Tuition exchange is a part of the benefit plan of the faculty member.) Colleges have preferences over matchings. We assume only

---

\(^1\)The theory and design of two-sided matching markets, such as entry-level labor markets for young professionals, online-dating markets, or college admissions, have been one of the cornerstones of market design for more than thirty years (see Gale and Shapley, 1962; Roth, 1984; Roth and Peranson, 1999; Hitsch, Hortacsu, and Ariely, 2010). Moreover, the theory of these markets has some important applications in allocation problems such as student placement and school choice (see Balinski and Sönmez, 1999; Abdulkadiroğlu and Sönmez, 2003).

\(^2\)See Section 2 for details of these applications.
a weak structure for these preferences. Colleges’ preferences over the incoming class is assumed to be responsive to their strict preferences over individual students. Moreover, their preferences over matchings are determined through their preferences over the incoming class and how balanced the eventual matching is.\(^3\) We start by showing, through a simple example, that individual rationality and non-wastefulness, standard concepts in two-sided matching markets, and balancedness are in general conflicting requirements (Proposition 1). For this reason, we restrict our attention to the set of balanced–efficient mechanisms. Unfortunately, there exists no balanced–efficient and individually rational mechanism that is immune to preference manipulation for colleges (Theorem 2).

We propose a new two-sided matching mechanism that is balanced-efficient, student group–strategy-proof, acceptable, respecting internal priorities,\(^4\) individually rational, and immune to quota manipulation by colleges (Theorems 1, 3, and 4). We also show that it is the unique mechanism satisfying the first four properties (Theorem 5). To our knowledge, this is one of the first papers using axiomatic characterization in the context of practical market design.

The outcome of this mechanism can be computed with a variant of David Gale’s top–trading–cycles (TTC) algorithm (Shapley and Scarf, 1974). In the school choice problem (cf. Abdulkadiroğlu and Sönmez, 2003) and the house allocation problem with existing agents (cf. Abdulkadiroğlu and Sönmez, 1999), variants related to Gale’s TTC, have been introduced and their properties have been extensively discussed (also see Pápai, 2000). In all of these problems, one side of the market is considered to be objects to be consumed that are not included in the welfare analysis. Schools and houses have no preferences but have “priorities”. Moreover, they are not strategic agents. In two-sided matching via exchange, in contrast to school choice and house allocation, both sides of the market are strategic agents and must be included in the welfare analysis. Based on these variants of Gale’s TTC, we formulate our algorithm, and thus, we refer to the induced mechanism as the two—sided top trading cycles (2S-TTC). As far as we know, this is the first time a TTC–variant algorithm has been used to find the outcome of a two-sided matching mechanism.\(^5\)

\(^3\)We do not rule out colleges having more complex preferences over which students they send out.

\(^4\)A mechanism respects internal priorities if, after a college increases the number of sponsored students, every student who was initially sponsored by that college and matched continues to be matched (although not necessarily with the same college).

\(^5\)Ma (1994) had previously characterized the core of a house exchange market, which can be found by Gale’s TTC algorithm, when there is a single seat at each school through Pareto efficiency, individual rationality, and strategy-proofness for students. Our characterization uses a proof technique different not only from Ma (1994), but also subsequent simpler proofs of this prior result by Sönmez (1995) and Svensson (1999). There are a few other TTC-related characterization results in the literature: Abdulkadiroğlu and Che (2010); Dur (2012); Morrill (2013) characterize school choice TTC a la Abdulkadiroğlu.
Although 2S-TTC is balanced–efficient, it may not match the maximum possible number of students while maintaining balance. We show that if the maximal-balanced solution is different from the 2S-TTC outcome even for one preference profile, it can be manipulated by students (Theorem 6).

Some tuition exchange programs require keeping a balance in a moving three-year window for their member colleges. For this reason, we extend our model to a dynamic setting, where colleges can have tolerable yearly imbalances. We propose an extension, two-sided tolerable top-trading-cycle (or 2S-TTTC) mechanism, which allows one to keep the imbalance of each college between some upper and lower bounds, and these bounds can be adjusted over the years. Once the bound-setting and adjustment processes are externally set, we show that 2S-TTTC keeps good properties of 2S-TTC: it is student-strategy-proof, acceptable, and respecting internal priorities; moreover, no acceptable matching within the balance limits can Pareto dominate its outcome.\(^6\)

As the last part of our analysis of tuition-exchange programs, in Appendix I, we compare the performances of 2S-TTC and 2S-TTTC with that of the best-case scenario of the current practice of tuition exchange with a wide range of simulations.\(^7\) By considering different degrees of correlation among students’ and also colleges’ preferences, and different yearly imbalance tolerance levels, we show that 2S-TTC and its variant match considerably more students to colleges and increase students’ welfare over the naive student-proposing deferred acceptance outcome, the best case scenario for the current market.\(^8\) This is a best-case scenario for the decentralized market as it minimizes coordination failures and ignores possible college incentives to underreport their certification quotas.\(^9\) Moreover, Combe, Tercieux, and Terrier (2016) conducted an empirical study

6 The closest in the literature to 2S-TTTC’s algorithm is the top–trading–cycles–and–chains (TTCC) algorithm proposed by Roth, Sönmez, and Ünver (2004); however, the use and facilitations of “chains” are substantially different in this algorithm than in 2S-TTTC.

7 We also develop a model of current semi-decentralized practice in tuition exchange in Appendix A. We show that balancedness is not in general achieved through decentralized market outcomes, jeopardizing the continuation and success of such markets. We define stability for particular externalities in college preferences. We show that stable matchings exist when colleges have plausible preferences over matchings (Proposition 3). Moreover, Proposition 4 implies that stability and balancedness are incompatible. Then we show that stability discourages exchange and can prevent the market from extracting the highest gains from exchange (see Theorems 10 and 11).

8 It is the best case, since in the Appendix A, we show that under reasonable assumptions, the current market gives incentives to decrease the quotas of agents.

9 It should be noted that there could be other market structures not governed by our simulation.
using teacher assignment data from France using a model related to ours. Compared to deferred-acceptance–based current practice, they show that a TTC-based approach doubles the number of teachers moving from their initial assignment. Additionally, when the distribution of the ranks of teachers over the schools are considered, the outcome of the TTC-based approach stochastically dominates that of the current practice. Thus, there exist real-life settings, in which our proposals can lead to significant welfare improvements.

We extend this model for temporary worker exchanges, such as teacher-exchange programs. We tweak our model slightly and assume that the quotas of the firms are fixed at the number of their current employees, and, hence, firms would like to replace each agent who leaves. We also assume that firm preferences are coarser than colleges in tuition exchange due to the temporary nature of the exchanges. We assume they have weakly size-monotonic preferences over workers: larger groups of acceptable workers are weakly better than weakly smaller groups of acceptable workers when the balance of the matching with larger groups of acceptable workers is zero and the balance of the matching with smaller group of worker is non-positive. In this model, we prove that 2S-TTC not only carries all of its previous properties through but also is strategy-proof for the firms, making it a very viable candidate (Theorem 9). Our aforementioned characterization also holds in this model.

2 Applications

2.1 Tuition Exchange

Some of the best-documented matching markets with a balancedness requirement are tuition-exchange programs in US. These are semi-decentralized markets, and some have failed over the years because of problems related to imbalanced matching activity.

It has been difficult for small colleges and universities to compete with bigger schools in trying to hire the best and brightest faculty. Colleges located farther away from major metropolitan areas face a similar challenge. Tuition-exchange programs play a prominent role for these colleges in attracting and retaining highly qualified faculty.11

---

10 Weakly size-monotonic preferences are weaker than dichotomous preferences (in absence of externalities), which are widely used in the matching literature, see for example Bogolomiaia and Moulin (2004), Roth, Sönmez, and Ünver (2005), Roth, Sönmez, and Ünver (2007), Ekici (2011), and Sönmez and Ünver (2014).

11 “Tuition Exchange enables us to compete with the many larger institutions in our area for talented faculty and staff. The generous awards help us attract and retain employees, especially in high-demand
Many colleges give qualified dependents of faculty tuition waivers. Through a tuition-exchange program, they can use these waivers at other colleges and attend these colleges for free. The dependent must be admitted to the other college. Tuition exchange has become a desirable benefit that adds value to an attractive employment package without creating additional out-of-pocket expenses for colleges; that is, colleges do not transfer money to each other for accepting their faculty’s dependents.

One of the prominent programs is “The Tuition Exchange, Inc.” (TTEI), which is also the oldest and largest of its kind.12

Each participating college to TTEI establishes its own policies and procedures for determining the eligibility of dependents for exchange and the number of scholarships it will grant each year. Each member college has agreed to maintain a balance between the number of students sponsored by that institution (“exports”) and the number of scholarships awarded to students sponsored by other member colleges (“imports”). Colleges aim to maintain a one-to-one balance between the number of exports and imports. In particular, if the number of exports exceeds the number of imports, then that college may be suspended from the tuition-exchange program. In order not to be suspended from TTEI, colleges often set the maximum number of sponsored students in a precautionary manner. Many colleges explicitly mention in their application documents that in order to guarantee their continuation in the program, they need to limit the number of sponsored students.13 As a result, in many cases not all qualified dependents are sponsored.

A tuition-exchange program usually functions as follows: each college determines its quotas, which are the maximum number of students it will sponsor (its “eligibility quota”) and the maximum number it will admit (its “import quota”) through the program. Then, the eligible students apply to colleges, and colleges make scholarship decisions based on preferences and quotas. A student can get multiple offers. She declines all but one, and, if possible, further scholarship offers are made in a few additional rounds. Students who are not sponsored cannot participate in the program, and hence do not receive a tuition-exchange scholarship. In the end, neither a student that is accepted by another college nor the home institution of the student pays tuition. The admitting institution de facto awards a tuition waiver to the dependent of the faculty of another college.

---

12See http://www.tuitionexchange.org. Through TTEI, 7,000 scholarships were awarded in 2015-2016, with annual value of $34,000 per scholarship that is paid as a tuition reduction. Despite TTEI’s large volume, other tuition exchange programs clear more than 50% of all exchange transactions in the US. In Appendix C, we describe the features of prominent tuition exchange programs.

13Lafayette College, Daemen College, DePaul University, and Lewis University are just a few examples.
2.2 Temporary Worker Exchanges

The balancedness requirement also matters in *temporary worker-exchange programs* (such as those for teachers, students, academic staff, and medical doctors). The Commonwealth Teacher Exchange Programme (CTEP), Fulbright Teacher Exchange Program, Erasmus Student Exchange Program, and the exchange program of International Federation of Medical Students’ Associations (IFMSA) are just a few examples. Some of these have been running for decades, and thousands of participants benefit from these worker exchange programs annually. Every year more than 10,000 medical students and 200,000 college students around the world participate in IFMSA’s and Erasmus’ exchanges, respectively. The main difference between these programs and tuition exchange is that (1) most exchange appointments are temporary, typically lasting one year, and (2) the workers are currently employed by their associated firms, so if they cannot be exchanged, they will continue to work in their current jobs.

2.3 Importance of Balancedness Requirement

Although two-sided matching via exchange induces a two-sided matching market, workers (students) cannot participate in market activity unless their home firms (colleges) sponsor them. Hence, an import/export balance emerges as an important feature of sustainable outcomes, as there are no monetary transfers between parties and there are costs for colleges associated with providing students. Balance requirements are the most important feature of these markets that distinguishes them from the previously studied matching markets. We illustrate three cases in which the absence of a balanced exchange led to the failure of the exchange program in different contexts.

The Northwest Independent Colleges Tuition Exchange program was founded in 1982 and included five members. Unlike TTEI, the colleges were not able to limit their exports. Because of sizable imbalances between imports and exports, members agreed to dissolve the program, and it stopped accepting new applicants after Fall 2015 in its current form.

---

14 There are also small bilateral staff-exchange programs. See Appendix D for details.
15 CTEP, which allows participants to exchange teaching positions and homes with a colleague from the UK, Australia, or Canada, has been running for 100 years. See http://www.cyec.org.uk/exchanges/commonwealth-teacher-exchange.
17 When we talk about balancedness in this paper, we are not strictly talking about zero-balance conditions where imports and exports even each other out. The idea can also be relaxed in static and dynamic manners to attain an approximate balance over time. Indeed, there could be gains for intertemporal trades and our proposals also address these issues in Section 4.2.
18 See https://www.insidehighered.com/news/2012/02/15/tuition-exchange-program-northwest-
The Jesuit universities exchange program FACHEX is another that was adversely affected. It included prominent universities such as Georgetown and Boston College. The program still does not have an embedded balancedness requirement. As a result, Georgetown abandoned the program a number of years ago.

The Erasmus student exchange program among universities in Europe is another example of a market in which a lack of balancedness have caused some exchange relationships to be terminated. Member colleges that want to exchange students with each other sign bilateral contracts that set the maximum number of students to be exchanged in certain years. The renewal decision of the contract depends on whether a reasonable balance is maintained between the incoming and outgoing exchange students between these colleges. In particular, if one of the colleges has more incoming students than its outgoing students, then that college does not renew the contract.

Tuition- and worker-exchange markets are closely related to favor markets, also known as “time banks,” where time spent doing a favor or the number of favors is used as the currency of exchange. Holding of the transaction currency in such markets corresponds to a positive imbalance in our model. If not enough currency is injected initially to the system and there is too much uncertainty, agents may shy away from using their currency. Baby sitting co-ops are a leading example of such time banks. Such banks could be adversely affected by the lack of balanced clearing mechanisms that clear all favors in a well-defined sufficiently long time period ahead of the time.\(^{19}\)

3 Two–Sided Matching via Exchange: Model

We introduce our model and the desirable solution concepts.\(^{20}\) Let \(C\) and \(S\) be the finite set of colleges and students, respectively. Set \(S\) is partitioned into \(|C|\) disjoint sets, i.e. \(S = \bigcup_{c \in C} S_c\) where \(S_c\) is the set of students who are applying to be sponsored by \(c \in C\). Let \(q = (q_c)_{c \in C} \in \mathbb{N}^{|C|}\) be the (scholarship) admission quota vector, where \(q_c\) is the maximum number of students who will be admitted by \(c\) with tuition exchange scholarship, and \(e = (e_c)_{c \in C} \in \mathbb{N}^{|C|}\) be the (scholarship) eligibility quota vector, where \(e_c\) is the number of students in \(S_c\) certified eligible by \(c\). Let \(\succ_C = (\succ_c)_{c \in C}\) be the list

\(^{19}\)In the mid-1970s, at the Capitol Hill Baby-Sitting Coop in Washington, DC, negative–balance aversion of families resulted in imbalances between families and decreased the number of favor exchanges between families. For details see http://www.ft.com/cms/s/2/f74da156-ba70-11e1-aa8d-00144feabdc0.html reached on Feb 20, 2016. This fits our setting perfectly: if the matches could be done in a monthly schedule using a centralized method, then balancedness requirements could be easily addressed.

\(^{20}\)We will keep tuition exchange in mind in naming our concepts. The minor differences in the temporary worker-exchange model will be highlighted in Section 5.
of college internal priority orders, where $\succ_c$ is a linear order over $S_c$ based on some exogenous rule. We denote the set of eligible students that are certified eligible by $c$ by $E_c$ where $E_c = \{s \in S_c \mid r_c(s) \leq e_c\}$ and $r_c(s)$ is the rank of $s \in S_c$ under $\succ_c$. Let $E = \bigcup_{c \in C} E_c$. The unassigned option, named the null college, is denoted by $c_0$ and $q_{c_0} = |S|$.

A matching is a correspondence $\mu : C \cup S \rightarrow C \cup S \cup c_0$ such that: \(^{21}\) (i) $\mu(c) \subseteq S$ where $|\mu(c)| \leq q_c$ for all $c \in C$, (ii) $\mu(s) \subseteq C \cup c_0$ where $|\mu(s)| = 1$ for all $s \in S$, (iii) $s \in \mu(c)$ if and only if $\mu(s) = c$ for all $s \in C$ and $s \in S$, and (iv) $\mu(s) = c_0$ for all $s \notin E$. \(^{22}\)

Let $M$ be the set of matchings. Let $X^\mu_c = \{s \in S_c \mid \mu(s) \in C \setminus c\}$ be the set of exports for $c$ under $\mu$. \(^{23}\) Let $M^\mu_c = \{s \in S \setminus S_c \mid \mu(s) = c\}$ be the set of imports for $c$ under $\mu$. Let $b^\mu_c \in \mathbb{R}$ be the net balance of $c \in C$ in $\mu$. We say $c \in C$ has a zero (negative) [positive] net balance in $\mu$ if $b^\mu_c = 0$ ($b^\mu_c < 0$) [$b^\mu_c > 0$].

Let $\succ_c = (\succ_c, \succeq_c) = ((\succ_c)_{s \in S}, (\succeq_c)_{c \in C})$ be the list of student and college preferences over matchings, where $\succ_c$ is the preference relation of agent $i \in S \cup C$ on $M$. We denote the strict preference of agent $i \in S \cup C$ on $M$ by $\succ_i$ and her indifference relation by $\sim_i$.

Each $s \in S$ cares only about her own match in a matching and has a strict preference relation $P_s$ on $C \cup c_0$. Let $R_s$ denote the at–least–as–good–as relation associated with $P_s$ for any student $s \in S$: $cR_sc$ if $cP_s c$ or $c = c$ for all $c, c' \in C \cup c_0$. Student $s$’s preferences over matchings $\succ_c$ is defined as follows: if $\mu(s)R_s\mu'(s)$ then $\mu \succ_c \mu'$.

On the other hand, each college potentially cares not only about its admitted class of (scholarship) students but also about its net balance. Colleges do not consider all students worth awarding a scholarship. \(^{24}\) To explain how colleges compare two matchings with the same balance, we need a ranking for each college over the sets of admitted students. The preference relation of $c$ over matchings, $\succ_c$, is defined through a linear order, denoted by $P_c$, over $S \cup \{\emptyset\}$. Let $P^*_c$ be the responsive (Roth, 1985) ranking of $c$ over the subsets of students; that is, $\forall T \subseteq S$ with $|T| < q_s$ and $s, s' \in S \setminus T$: (1) $sP_c\emptyset \implies (T \cup s) P^*_c T$ and (2) $sP_c s' \implies (T \cup s) P^*_c (T \cup s')$. Note that $P^*_c$ is just a ranking over the sets of admitted students and is not the preference relation of $c$ over matchings. Let $R^*_c$ be the weak ranking over the subset of students induced by $P^*_c$. Throughout the paper we assume that between any two matchings in which $c$ has the same net balance, it prefers the one with the higher-ranked set of admitted students according to $R^*_c$. Formally, for any $c \in C$, college $c$’s preferences over matchings, $\succ_c$, satisfies the following restriction: for any $\mu, \nu \in \mathcal{M}$, if $b^\mu_c = b^\nu_c$ and $\mu(c) R^*_c \nu(c)$ then $\mu \succ_c \nu$.

\(^{21}\)We may refer to singleton $\{x\}$ as $x$ with a slight abuse of notation. The only exception is $\{\emptyset\}$.

\(^{22}\)In tuition exchange, only the students who are certified eligible can be assigned to other institutions. Therefore, if $s$ is not certified eligible, i.e., if $s \in S \setminus E$, then she will be assigned to the null college.

\(^{23}\)When we say $s \in S$ is matched to $c \in C$, we mean $s$ receives a tuition-exchange scholarship from $c$.

\(^{24}\)We say a student $s$ is unacceptable for college $c$ if $c$ does not consider $s$ worth awarding a scholarship and $s$ is acceptable for $c$ otherwise.
We now introduce the properties of desirable matchings. A matching \( \mu \in \mathcal{M} \) Pareto dominates \( \nu \in \mathcal{M} \) if \( \mu \succeq_i \nu \) for all \( i \in C \cup S \) and \( \mu \succ_j \nu \) for some \( j \in C \cup S \). A matching \( \mu \) is Pareto efficient if it is not Pareto dominated by any other \( \nu \in \mathcal{M} \). A matching \( \mu \in \mathcal{M} \) is acceptable if \( s P_c \emptyset \) and \( c P_s c_\emptyset \) for all \( c \in C \) and \( s \in \mu(c) \).

A matching \( \mu \in \mathcal{M} \) is balanced if \( b^c_\emptyset = 0 \) for all \( c \in C \). Balance is the key property in a tuition-exchange market. For each tuition-exchange market, the set of balanced matchings is nonempty. For instance, a matching where all students are unassigned satisfies balancedness. Moreover, there may exist multiple balanced matchings for a given market. We say a balanced matching \( \mu \) is balanced-efficient if it is not Pareto dominated by any other balanced matching.

We say \( \mu \) is blocked by a college \( c \in C \) if there exists some \( \mu' \in \mathcal{M} \) such that \( \mu' \succeq_c \mu \), \( \mu'(s) = \mu(s) \) for all \( s \in S \setminus \mu(c) \), and \( \mu'(c) \subset \mu(c) \). A matching \( \mu \) is blocked by a student \( s \in S \) if \( c_\emptyset P_s \mu(c) \). A matching \( \mu \) is individually rational if it is not blocked by any individual agent. A matching \( \mu \) is nonwasteful if there does not exist a pair \( (c,s) \) such that \( |\mu(c)| < q_s \), \( c P_s \mu(s) \) and \( \mu' \succ_{c} \mu \), where \( \mu'(s) = c \) and \( \mu'(s') = \mu(s') \) for all \( s' \in S \setminus s \). In Appendix A, we provide an analysis of the decentralized practice of tuition exchange and “stability”, defined there for a market with externalities.

Throughout the paper, \( C, S, \) and \( r_C \) are fixed; a quota vector, eligibility vector, and a preference profile defines a tuition-exchange market – or simply, a market – as \([q,e,\succeq] \).

### 3.1 Tuition-Exchange Mechanisms

The current practice of tuition exchange is implemented through indirect semi-decentralized market mechanisms. Although our new proposal can also be implemented indirectly, it will be useful to discuss it as a direct mechanism to analyze its properties. A (direct) mechanism is a systematic way of selecting a matching for each market. Let \( \phi \) be a mechanism; then the matching selected by \( \phi \) in market \([q,e,\succeq] \) is denoted by \( \phi[q,e,\succeq] \), and the assignment of agent \( i \in S \cup C \) is denoted by \( \phi[q,e,\succeq](i) \).

In a revelation game, students and colleges report their preferences; additionally, colleges report their admission and eligibility quotas.\(^{26}\) A mechanism \( \phi \) is immune to preference manipulation for students (or colleges) if for all \([q,e,\succeq] \), there exists no \( i \in S \) (or \( i \in C \)) and \( \succeq'_i \) such that \( \phi[q,e,(\succeq'_i,\succeq_{-i})](i) \succ_i \phi[q,e,\succeq](i) \). A mechanism \( \phi \) is immune to preference manipulation if it is immune to preference manipulation for both students and colleges. A mechanism \( \phi \) is immune to quota manipulation if for

\(^{25}\)Note that \( b^c_\emptyset \geq 0 \) for all \( c \in C \) and \( b^c_s \leq 0 \) for all \( c \in C \) imply \( b^c_\emptyset = 0 \) for all \( c \in C \).

\(^{26}\)Since the internal priority order is exogenous, the set of eligible students can be determined by the eligibility quota.
all \([q, e, \succeq]\), there exists no \(c \in C\) and \((q_c', e_c') \in \mathbb{N}^2\) such that \(\varphi[(q_c', q_c), (e_c', e_c), \succeq](c) \succ_c \varphi[q, e, \succeq](c)\). A mechanism \(\varphi\) is \textbf{strategy-proof for colleges} if for all \([q, e, \succeq]\), there exists no \(c \in C\) and \((q_c', e_c', \succeq_c')\) such that \(\varphi[(q_c', q_c), (e_c', e_c), (\succeq_c', \succeq_c')](c) \succ_c \varphi[q, e, \succeq](c)\). A mechanism is \textbf{strategy-proof for students} if it is immune to preference manipulation for students. A mechanism is \textbf{strategy-proof} if it is strategy-proof for both colleges and students.\(^{27}\)

One distinctive feature of the tuition-exchange market is the existence of internal priorities for each \(c \in C\), \(\succ_c\). In current practice, the internal priority order is used to determine which students will be certified eligible. This priority order is usually based on the seniority of faculty members. We incorporate this priority-based fairness objective into our model by introducing a new property. It is desirable that whenever a student \(s\) sponsored by \(c\) is assigned to a college in \(\varphi[q, e, \succeq]\), she should also be assigned in \(\varphi[(\tilde{q}_c, q_c), (\tilde{e}_c, e_c), \succeq]\) where \(\tilde{e}_c > e_c\) and \(\tilde{q}_c \geq q_c\). That is, the addition of students with lower internal priority should not cause \(s\) to be unassigned. Formally, a mechanism \(\varphi\) \textbf{respects internal priorities} if whenever a student \(s \in S_c\) is assigned to a college in market \([q, e, \succeq]\), then \(s\) is also assigned to a college in \([(\tilde{q}_c, q_c), (\tilde{e}_c, e_c), \succeq]\) where \(\tilde{e}_c > e_c\) and \(\tilde{q}_c \geq q_c\).\(^{28}\) Respect for internal priorities is a fairness notion rather than efficiency.

\section*{4 Two–Sided Top Trading Cycles}

In this section, we propose a mechanism that is individually rational, acceptable, balanced–efficient, and strategy-proof for students. Moreover, it respects colleges’ internal priorities. Throughout our analysis, we impose a weak restriction on college preferences. Assumption 1 below states that a college prefers a better scholarship class with zero net balance to an inferior scholarship class with a nonpositive net balance.

\textbf{Assumption 1} \textit{For any }\mu, \nu \in \mathcal{M}\textit{ and }c \in C\textit{, if }b_c^\mu = 0\textit{, }b_c^\nu \leq 0\textit{, and }\mu(c) P^*_c\nu(c)\textit{ then }\mu \succ_c \nu.\textit{ }

We start with the following proposition, which shows the incompatibility between balancedness and individual rationality, and nonwastefulness.

\textbf{Proposition 1} \textit{Under Assumption 1, there may not exist an individually rational and nonwasteful matching that is also balanced.}\(^{29}\)

\(^{27}\)Since students care only about the colleges they are matched with, it will be sufficient for them to report their preferences over colleges. Under an additional assumption, our proposal in Section 4 can also be implemented by having colleges only report individual students as “acceptable” or “unacceptable”.

\(^{28}\)This property is used in our characterization in Section 4 where we show that this axiom does not bring additional cost to our proposed mechanism (Theorem 6).

\(^{29}\)All proofs are in Appendix B.
Proposition 1 also shows that there exists no stable and balanced mechanism.\(^{30}\)

It will be useful to denote a matching as a directed graph, as we will find the outcome of our mechanism through an algorithm over directed graphs. In such graphs, colleges and students are nodes; a directed edge is between a college and a student, and it points to either the college or the student, but not both. Given a matching \(\mu\), let each \(s \in S\) point to \(\mu(s)\) and each \(c \in C\) point to all its matched sponsored students, i.e., those in \(S_c \setminus \mu(c)\); moreover, let \(c_\emptyset\) point to students in \(\mu(c_\emptyset)\). In this graph, we define the following subgraph: A **trading cycle** consists of an ordered list of agents \((c_1, s_1, c_2, s_2, \ldots, c_k, s_k)\) such that \(c_1\) points to \(s_1\), \(s_1\) points to \(c_2\), \ldots, \(c_k\) points to \(s_k\) and, \(s_k\) points to \(c_1\).

In the following Remark, we state that if a matching is balanced, then we can decompose it into a finite number of disjoint trading cycles. We skip its proof for brevity.

**Remark 1** A matching \(\mu\) is balanced if and only if each student is in a trading cycle in the graph of the matching.

We are ready to propose a new two-sided matching mechanism. We will find its outcome using an algorithm inspired by top–trading–cycles (TTC) introduced for one–sided resource allocation problems, such as for school choice (by Abdulkadiroğlu and Sönmez, 2003) and dormitory room allocation (by Abdulkadiroğlu and Sönmez, 1999). These TTC algorithms were inspired by *Gale’s TTC algorithm* (Shapley and Scarf, 1974), which was used to find the core allocation of a simple exchange economy, referred to as the *housing market*, a subclass of one-sided matching problems. Most common mechanisms in one-sided matching problems function through algorithms that mimic agents exchanging objects that are initially allocated to them either through individual property rights or through the mechanism’s definition of the agents (see also Pápai, 2000; Pycia and Ünver, 2016). In contrast, in our market, college slots are not objects. Therefore our definition of a mechanism, and the properties of matchings and mechanisms (except strategy-proofness for students) do not have any analogous translation in such problems. However, because we use a variant of TTC algorithm to find the outcome, we refer to our mechanism as **two–sided (student–pointing) top–trading–cycles (2S-TTC)**. Its outcome is found for any given \([q,e,\succ]\) as follows:\(^{31}\)

\(^{30}\)A matching is stable if it is individually rational and not blocked by a college-student pair. In our setting with externalities, it is formally defined in Appendix A.

\(^{31}\)The converse of this process, using an algorithm originally introduced for two-sided matching markets in one-sided matching markets, has already been utilized in market design. For certain real-life one-sided problems regarding student placement and school choice, Balinski and Sönmez (1999) introduced and Abdulkadiroğlu and Sönmez (2003) the student–optimal stable mechanism, whose algorithm was originally introduced to find stable matchings in two-sided matching markets by Gale and Shapley (1962). Later on, many school districts in the US adopted this mechanism for public school admissions (see Abdulkadiroğlu, Pathak, Roth, and Sönmez, 2005 and Abdulkadiroğlu, Pathak, and Roth, 2005).
**The Algorithm for the Two-Sided Top-Trading-Cycles Mechanism:**

Round 0: Assign two counters, for admission and eligibility, for each college \( c \in C \), and set them equal to \( q_c \) and \( e_c \), respectively.

**Round** \( k \geq 1 \): Each remaining student points to her favorite college among the remaining ones in \( C \cup c_\emptyset \) that considers her acceptable, and each remaining \( c \in C \) points to the student in \( S_c \) among the remaining ones who has the highest priority in \( p_c \). Null college \( c_\emptyset \) points to the students pointing to it. Due to the finiteness of the sets of the colleges and students, there exists at least one trading cycle. Each agent can be part of at most one cycle. Every student in each cycle is assigned a seat at the college she is pointing to and removed. If the cycle does not contain \( c_\emptyset \), then the counters of each college in that cycle are reduced by one. If the cycle contains \( c_\emptyset \), then we reduce only the eligibility counter of the college whose student is in that cycle. If any counter of a college reaches zero, then that college is removed and its remaining students are assigned to \( c_\emptyset \).

The algorithm terminates when there are no remaining students in the market.

In the following theorem, we show that 2S-TTC is balanced-efficient, acceptable, and individually rational, and it respects internal priorities.

**Theorem 1** Under Assumption 1, 2S-TTC is an individually rational, balanced-efficient, and acceptable mechanism that also respects internal priorities.

It should be noted that balanced-efficiency of 2S-TTC is not directly implied by (Pareto) efficiency of TTC in a one-sided market. Here, colleges are players with multiple seats. Observe that by assigning a college at least one highly preferred student and some unacceptable ones, some acceptable, individually rational, and balanced matchings can potentially be (weakly) improved for everyone while keeping balancedness intact (and even the number of students who are assigned to a college can go up). In this theorem, through an iterative approach, we show that it is not possible to improve over 2S-TTC’s outcome in such a fashion. Also consider the following concept: For any \( I \subseteq S \cup C \), a balanced matching is balanced-efficient for \( I \) if there is no other balanced matching which makes each agent in \( I \) weakly better off and at least one agent in \( I \) strictly better off. 2S-TTC mechanism is neither balanced-efficient for students nor balanced-efficient for colleges. However, it is balanced-efficient overall (when all agents’ welfare is taken into account). Thus, it is a compromise between the welfare of both sides, slightly favoring students by construction. Since side-balanced-efficiency is not satisfied by 2S-TTC in general (even under strict preferences), we need a new proof to prove its overall balanced-efficiency. To illustrate that 2S-TTC is not balanced-efficient for any side, we provide a simple example in Appendix G and further explanation regarding why previously known results do not immediately imply our efficiency result.
Under a centralized mechanism, incentives for participants to truthfully reveal their preferences are desirable. Unfortunately, we show that balanced-efficiency, individual rationality, and immunity to preference manipulation for colleges are incompatible.

**Theorem 2** There does not exist an individually rational (or acceptable) and balanced-efficient mechanism that is also immune to preference manipulation for colleges.

We prove this theorem by constructing several small markets and showing that it is not possible to satisfy all three properties in one of these markets.

Theorem 1 and 2 imply that the 2S-TTC mechanism is not strategy-proof for colleges.

The following theorem shows that it is group strategy-proof for students. This result is a consequence of TTC being group strategy-proof in a housing market (cf. Pápai, 2000).

**Theorem 3** 2S-TTC is group strategy-proof for students.

2S-TTC can be run as an indirect mechanism where colleges report only their acceptable incoming students. Hence, the strategy space for the colleges is very simple in using 2S-TTC in the field: their strategy is to report their admission and eligibility quotas and their sets of acceptable students based on their preferences over the matchings, set of own students, and internal priority order.

Moreover, if we focus on the game played by the tuition-exchange office of a college, when admissions preferences are fixed, truthful admission quota revelation and certification of all its own students is a (weakly) dominant strategy under 2S-TTC.\(^{32}\)

**Theorem 4** Under Assumption 1 and when true eligibility quotas satisfy \(e_c = |S_c|\) for all \(c \in C\), 2S-TTC is immune to quota manipulation.

We prove the theorem with a lemma showing that as the quotas of a college increase, the import and export sets of this college also expand under 2S-TTC.\(^ {33}\)

Theorems 3 and 4 point out that only colleges can benefit from manipulation, and they can manipulate the 2S-TTC mechanism by misreporting their preferences. Moreover,

\(^{32}\)On their websites, colleges explain that the sole reason for certifying a limited number of students is maintaining a balanced exchange. 2S-TTC removes the need for this rightful caution associated with the current market practices (see Appendix A).

\(^{33}\)Theorem 4 is in stark contrast with similar results in the literature for stable mechanisms. The student– and college–optimal stable mechanisms are prone to admission quota manipulation by the colleges even under responsive preferences (see Sönmez, 1997 and Konishi and Ünver, 2006) Thus, 2S-TTC presents a robust remedy for a common problem seen in centralized admissions that use the student–optimal stable mechanism and also in tuition exchange in a decentralized market (see Theorems 10 and 11 in Appendix A).
the only way to manipulate preferences is to report an acceptable student as unacceptable. Suppose we take all the admitted students in the regular admission procedure as acceptable for a tuition-exchange scholarship. Then, to manipulate the 2S-TTC mechanism, a college needs to reject a student who satisfies the college admission requirements. Usually college admission decisions are made before the applicants are considered for scholarships.

Proposition 2 below implies that colleges do not benefit from misreporting their ranking over incoming classes.

**Proposition 2** Under Assumption 1, colleges are indifferent among strategies that report preferences over matchings in which the same set of students is acceptable under the 2S-TTC mechanism.

We have shown that 2S-TTC has appealing properties. In the following theorem, we show that it is the unique mechanism satisfying a subset of these properties.

**Theorem 5** Under Assumption 1, 2S-TTC is the unique student–strategy-proof, acceptable, and balanced–efficient mechanism that also respects internal priorities.

In the proof of our characterization theorem, we use a different technique from what is usually employed in elegant single quota characterization proofs such as Svensson (1999) and Sönmez (1995) for the result of Ma (1994). Our proof relies on building a contradiction with the claim that another mechanism with the four properties in the theorem’s hypothesis can exist. Suppose such a mechanism exists and finds a different matching than 2S-TTC for some market. The 2S-TTC algorithm runs in rounds in which trading cycles are constructed and removed. Suppose $S(k)$ is the set of students removed in Round $k$, while running the 2S-TTC algorithm in such a way that in each round only one arbitrarily chosen cycle is removed and all other cycles are kept intact. We find a Round $k$ and construct an auxiliary market with the following three properties: (1) Eligibility quotas of home colleges of students in $S(k)$ are set such that these are the last certified students in their respective home institutions; (2) all preferences are kept intact except those of students in $S(k)$, whose preferences are truncated after their 2S-TTC assignments; and (3) all students in $S(k)$ are assigned $c_\emptyset$ under the alternative mechanism, while all students removed in the 2S-TTC algorithm before Round $k$ have the same

---

34Our proposal also prevents some other manipulation possibilities. For example, right now if a college really likes one of its own students, then it may decrease its export quota preventing this student to be eligible, and the student, in the end, attends to her home college through tuition remission. However, in our proposal a college’s export quota also determines the set of its own students who are eligible for tuition remission. Thus, no ineligible student can attend her home college through tuition remission. We think that tuition exchange and tuition remission programs should be run together (see next subsection).
assignment under 2S-TTC and the alternative mechanism. This contradicts the balanced-efficiency of the alternative mechanism: we could give the students in $S(k)$ their 2S-TTC assignments while keeping all other assignments intact and obtain a Pareto-dominating balanced matching. Round $k$ and the auxiliary market are constructed in three iterative steps.

Among all the axioms, only the respect for internal priorities is based on exogenous rules. One might suspect that more students will benefit from the tuition-exchange program if we allow the violation of respect for internal priorities. However, such mechanisms turn out to be manipulable by students:

**Theorem 6** Any balanced and individually rational mechanism that does not assign fewer students than the 2S-TTC and selects a matching in which more students are assigned whenever such a balanced and individually rational outcome exists, is not strategy-proof for students, even under Assumption 1.

### 4.1 Market Implementation: Tuition Remission and Exchange

Incorporating tuition-remission programs by all participating colleges in tuition exchange is the best way to implement a centralized clearinghouse. If parallel remission and exchange programs are run, as in current practice, a student may receive multiple scholarship offer, one from her home college and one from the tuition-exchange program. If the student accepts the home college’s offer, the net balance of the college may deteriorate.

Although the current system is inflexible in accommodating this important detail, a clearinghouse utilizing 2S-TTC can easily combine tuition exchange with remission. Indeed, in Assumption 1, we allowed a college to deem its own sponsored students to be acceptable. Hence, all our results in this section robust to integration.

More specifically, we propose to run an indirect version of 2S-TTC in sequential stages in a semi-decentralized fashion: first, colleges announce their tuition-exchange scholarship quotas and which of their students are eligible to be sponsored for both exchange and remission; then, eligible students apply for scholarship to the colleges they find acceptable; then colleges send out scholarship admission letters. At this stage, as students have also learned their opportunities in the parallel-running regular college admissions market, they can form better opinions about the relative ranking of the null college, i.e., their options outside the tuition-exchange market. Students submit rankings over the colleges that admitted them with a tuition-exchange scholarship and the relative ranking of their outside option. Finally, 2S-TTC is run centrally to determine the final allocation.
4.2 Allowing Tolerable Imbalances

Some programs care about approximate balance over a moving time window. Here, we relax the zero-balance constraint and allow each \( c \in C \) to maintain a balance within an interval \( [\ell_c, u_c] \) where \( \ell_c \leq 0 \leq u_c \). When either \( \ell_c \) or \( u_c \) equals zero for all \( c \in C \), the problem turns into the case studied in Section 4. Let \((\ell_c, u_c)_{c \in C}\) be the tolerance profile.

When the colleges hold a non-zero balance, then there may exist some colleges exporting (importing) more than they import (export). Then, we cannot represent all allocations by cycles. Therefore we need to consider chains in addition to the cycles. A chain is an ordered list \((c_1, s_1, c_2, s_2, ..., c_k)\) such that \( c_1 \) points to \( s_1 \), \( s_1 \) points to \( c_2 \), ..., \( c_{k-1} \) points to \( s_{k-1} \) and \( s_{k-1} \) points to \( c_k \). We refer to \( c_1 \) as the tail and \( c_k \) as the head of the chain.

We use a mechanism similar to the 2S-TTC referred as the two-sided tolerable top-trading-cycles. For any problem and a tolerance profile, its outcome is found as follows:

**Two-Sided Tolerable Top Trading Cycles (2S-TTTC):**

**Step 0:** Fix an exogenous priority order among colleges. Assign two counters for each \( c \in C \), \( o^q_c \) and \( o^e_c \), and set them equal to \( q_c \) and \( e_c \), respectively. Let \( b_c \) track the current balance of \( c \) in the fixed portion of the matching. Initially set \( b_c = 0 \) for each \( c \in C \). Assign an export and an import counter for the null college and set them equal to \(|S|\). All colleges are marked as importing and exporting.

**Step 1a:**
* If \( o^e_c = 0 \) and either \( o^q_c = 0 \) or \( b_c = u_c \), then remove \( c \). If \( o^e_c = 0 \) and \( o^q_c > 0 \) and \( b_c < u_c \), then \( c \) becomes non-exporting.\(^{36}\)
* If \( o^q_c = 0 \) and \( b_c = \ell_c \), then remove \( c \). If \( o^q_c = 0 \) and \( o^e_c > 0 \) and \( b_c > \ell_c \) then \( c \) becomes non-importing.

**Step 1b:** Each student points to her favorite available importing college, which considers her acceptable, and each available exporting college \( c \) points to the student \( s \in S_c \) who has the highest internal priority among the available ones. The null college \( c_\emptyset \) points to the students pointing to it.

Proceed to Step 2 if there is no cycle. Otherwise locate each cycle, and assign each student to the college that she points to. Each assigned student is removed.

* The eligible student counter, \( o^e_c \), of each \( c \) that is in a cycle is reduced by one.
* The import counter, \( o^q_c \), of each \( c \) in a cycle is reduced by one.
* Return to Step 1a.

**Step 2:** If there are no students left, we are done. If not, then all chains end with...

\(^{35}\)Here, \( \ell_c \) and \( u_c \) are integers.

\(^{36}\)I.e., a college is non-exporting if it has available quota to import but all its sponsored students are removed. Therefore, a non-exporting college cannot point to a student.
non-exporting colleges. If \( b_c = \ell_c \) for each available exporting college \( c \), then remove all non-exporting colleges and go to Step 1a.\(^{37}\) Otherwise, find the chain whose tail has the highest priority among the available exporting colleges with \( b_c > \ell_c \). Assign each student in that chain to the college that she points to and remove her. Denote the tail and head of the chain by \( c_t \) and \( c_h \), respectively. Other colleges in the chain are represented by \( \tilde{c} \):

* The eligible student, \( o_{ct}^\varepsilon \), and import, \( o_{ch}^d \), counters of all \( \tilde{c} \) are reduced by one.
* Eligible student counter \( o_{ct}^\varepsilon \) and current balance \( b_{ct} \) are reduced by one.
* Import counter \( o_{ch}^d \) is reduced by one and current balance \( b_{ch} \) is increased by one.
* Return to Step 1a.

The algorithm terminates when there are no remaining eligible students left. We call each repetition of these steps a round.

The 2S-TTTC mechanism inherits the desired features of the 2S-TTC. In Theorem 7, we show that students cannot benefit from misreporting their preferences under 2S-TTTC and for any problem and tolerance profile \((\ell_c, u_c)_{c \in C}\) its outcome cannot be Pareto dominated by another acceptable matching \( \nu \) such that \( b_{ct}^\nu \in [\ell_c, u_c] \) for all \( c \in C \).

**Theorem 7** 2S-TTTC is strategy-proof for students and for any problem \([q, e, \succeq]\) and tolerance profile \((\ell_c, u_c)_{c \in C}\), there does not exist an acceptable matching \( \nu \) that Pareto dominates the outcome of 2S-TTTC and \( \ell_c \leq b_{ct}^\nu \leq u_c \) for all \( c \in C \).

In the 2S-TTTC mechanism, a student starts pointing to the colleges in her preference list after all the other students with higher internal rank are assigned to a college, including the null college. Moreover, a student points to the acceptable colleges that consider her acceptable. As a consequence, the 2S-TTTC mechanism satisfies acceptability and respects internal ranking.

**Theorem 8** 2S-TTTC is acceptable and respects internal priorities.

Theorem 7 and 8 hold without any assumption on preferences. Under a mild assumption on college preferences, we can show that 2S-TTTC is individually rational and it is a weakly dominant strategy for colleges to certify all their students.

Although 2S-TTTC is defined in a static problem, we can easily extend it to the dynamic environment where the aggregate balance over years matters. In particular, for each period \( t \) and \( c \in C \) we can set counter \( b_c \) equal to \( c \)'s aggregate balance in period \( t - 1 \) where the aggregate balance in period \( t - 1 \), is equal to the sum of balances between period 1 and \( t - 1 \). Moreover, the exogenous priority rule used in period \( t \) can be determined based on the aggregate balance colleges carry at the end of period \( t - 1 \) such that the highest priority can be given to the college with the highest aggregate balance and so on.

\(^{37}\)That is, no more chains respecting the tolerance interval can form after this point in the algorithm.
5 Temporary Worker Exchanges

Many organizations have temporary worker-exchange programs that can be modeled through our balanced two-sided matching framework. The first difference between such programs and tuition exchange is that these exchanges are temporary. Each firm usually requires a set of specific skills, e.g., a mathematics teacher to replace their own mathematics teacher. Compatibility and ability to perform the task are the main preference criterion rather than a strict preference ranking. E.g., finding a good teacher with a specific degree is the first-order requirement, rather than finer details about the rankings of all good teachers.

The second difference is that each position and each worker should be matched, unlike the tuition-exchange application. The workers are currently working for their home firms. Thus, the firms find these workers necessarily acceptable. By contrast, in tuition exchange, colleges are not required to admit all the dependents of their employees without a tuition-exchange scholarship. In temporary worker exchanges, a worker who does not want to go to a different firm necessarily stays employed in her home firm. Hence, we need to use a variant of the tuition-exchange model to facilitate balanced and efficient trade in such circumstances.

We can use the model introduced in Section 3, with slight changes. In Section 3, in the definition of a matching, students who are not eligible are taken as assigned to $c_\emptyset$. However, for worker-exchange programs, the workers who are not certified as eligible continue to work in their home firms in a matching. Formally, a matching is a correspondence $\mu : C \cup S \to C \cup S$ such that, (1) $\mu(c) \subseteq S$, where $|\mu(c)| \leq q_c$ for all $c \in C$, (2) $\mu(s) \subseteq C$, where $|\mu(s)| = 1$ for all $s \in S$, (3) $s \in \mu(c)$ if and only if $\mu(s) = c$ for all $c \in C$ and $s \in S$, and (4) $\mu(s) = c$ for all $s \in S_c \setminus E$. Let $\mathcal{M}$ be the set of all matchings.

To capture the features of worker-exchange programs, we make certain assumptions about the preferences of workers and firms. Since worker $s \in S_c$ is already working at firm $c$, we assume that $s$ finds $c$ acceptable and $c$ finds $s$ acceptable, i.e., $cP_sc_\emptyset$ and $sP_c\emptyset$ for all $s \in S_c$ and $c \in C$. As discussed above, acceptable workers do not have huge differences for the firms. The compatibility assumption and Assumption 1 together imply that each firm weakly prefers a matching with zero net–balance to another matching with non-positive balance as long as it gets weakly more acceptable workers under the former one. We formally state these assumptions on preferences as follows.

Assumption 2 (1) (Weakly size-monotonic firm preferences) For any $c \in C$ and $\mu, \nu \in \mathcal{M}$, if $b^c_\nu = 0$, $b^c_\mu \leq 0$ and $|\{s \in \mu(c) : sP_c\emptyset\}| \geq |\{s \in \nu(c) : sP_c\emptyset\}|$ then $\mu \succeq_c \nu$, and (2) (Acceptability of current match) For any $c \in C$ and any $s \in S_c$, $cP_sc_\emptyset$ and $sP_c\emptyset$. 

19
Based on Assumption 2, a balanced mechanism that allows employees to get better firms, which consider them acceptable, improves the total welfare without hurting anyone. Hence, 2S-TTC can be applied to temporary exchange programs. In this environment, 2S-TTC inherits its desired features, i.e., it is balanced-efficient, acceptable, and individually rational, and it respects internal priorities. Moreover, it is strategy-proof. The uniqueness result presented in Section 4 also holds in the worker-exchange market.

**Theorem 9** Under Assumption 2, 2S-TTC is a balanced–efficient, individually rational, acceptable, and strategy-proof mechanism that also respects internal priorities, and it is the unique balanced–efficient, acceptable, student strategy-proof mechanism that respects internal priorities.\(^{38}\)

An immediate corollary of Theorem 9 is that reporting true import quota and certifying all workers is a weakly dominant strategy for firms.

**Corollary 1** Under Assumption 2, 2S-TTC is immune to quota manipulation.

## 6 Conclusions

This paper proposes a centralized market solution to overcome problems observed in decentralized exchange markets. We used tuition exchange and temporary exchange programs as our leading examples, in which more than 300,000 people participate annually.

Our paper, besides introducing a new applied problem and proposing a solution to it, has six main theoretical and conceptual contributions: We introduce a new two-sided matching model that builds on the two most commonly used matching models in the literature: discrete object allocation, including school choice, and standard many-to-one two-sided matching models, but differs in many fronts from these. As far as we know, this is the first time object allocation and exchange algorithms inspire the mechanism design for a two-sided matching model. This is one of the few instances when axiomatic mechanism design is used in practical market design to come up with the correct mechanism. A natural axiomatic representation is given for a TTC-based mechanism. This is one of the rare occasions where the stable matching theory of Gale and Shapley is extended to a setting with externalities with tractable existence, equilibrium, and comparative static results (see Appendix A). Finally, our paper is one of the few studies that propose a dynamic matching mechanism with good properties for a dynamic applied problem.

\(^{38}\)Moreover, 2S-TTC is stable in this domain. This result is noteworthy, because the widely-used worker-proposing deferred-acceptance mechanism with exogenous tie-breaking is not balanced-efficient, although it is stable and balanced in this special environment. We also prove the stability of 2S-TTC in the proof of this theorem.

Appendices Intended for Online Publication

Appendix A  On Current Practice of Tuition Exchange

In this appendix, we analyze the current practice of tuition exchange. As the centralized process is loosely controlled, once each college sets its eligibility/admission quota and eligible students are determined, the market functions more like a decentralized one rather than a centralized one. Once colleges commit to the students they will sponsor, they lose their control over them. A sponsored student can sometimes get multiple offers and decide which one to accept and when to accept it. Hence, stability emerges as a relevant notion for a benchmark market-equilibrium concept when there is no other friction. To adopt stability in our model, we introduce blocking by a pair: We say \( \mu' \in \mathcal{M} \) is obtained from \( \mu \) by the mutual deviation of \( c \) and \( s \) if \( s \in \mu'(c) \subseteq \mu(c) \cup s \), and \( \mu'(s') = \mu(s') \) for all \( s' \in S \setminus (\mu(c) \cup s) \). A matching \( \mu \in \mathcal{M} \) is blocked by college-student pair \((c, s)\) if \( c \not\succ_{c} \mu(s) \) and \( \mu' \succ_{c} \mu \), where \( \mu' \in \mathcal{M} \) is obtained from \( \mu \) by the mutual deviation of \( c \) and \( s \). As in any blocking condition in cooperative games with externalities, we need to take a stance on how other players act when a pair deviates. We assume that only one college or one student deviates at a time, and assume that the rest of the students and colleges do not make simultaneous decisions.\(^3\)\(^9\) A matching \( \mu \) is stable if it is individually rational and not blocked by any college-student pair.

Tuition exchange market has some idiosyncratic properties different from those of previously studied two-sided matching markets.

In tuition exchange — in its current implementation — an admitted class of lower-quality students can be preferable to one with higher-quality students under two different matchings, if the latter one deteriorates the net balance of the college. The extreme version of this preference is a college being extremely averse towards negative net-balance matchings, regardless of the incoming class. Maintaining a nonnegative net balance is important for a college to continue its membership in the program. In particular, a college with negative net balance might be suspended from the program.

We will incorporate these features as two formal assumptions in this section. Assumption 3 states that a better admitted class is preferable as long as the net balance does not decrease, admission of unacceptable students deteriorates the rankings of matchings regardless of their net balances, and a college deems its own students unacceptable in tuition exchange. Assumption 4 introduces negative net-balance averse preferences. In

\(^3\)\(^9\)See Pycia and Yenmez (2015) for more discussion of this stability concept under matching problems with externalities.
all results in this section we will use Assumption 3, while Assumption 4 will be used in only one result. We start by stating Assumption 3.

**Assumption 3** For any $c \in C$ and $\mu, \nu \in \mathcal{M}$,

1. (Preference increases with a better admitted class and a non-deteriorating balance) if $b_c^\mu \geq b_c^\nu$ and $\mu(c)P^*c \nu(c)$, then $\mu \succ_c \nu$,

2. (Awarding unacceptable students exchange scholarships is not preferable) if there exists $s \in \nu(c) \setminus \mu(c)$, $\emptyset P_c s$ and $\nu(s') = \mu(s')$ for all $s' \in S \setminus s$, then $\mu \succ_c \nu$, and

3. (Unacceptability of the college’s own students for exchange scholarships) $\emptyset P_c s$ for all $s \in S_c$.

Assumption 3 implies that, if there exists $s \in \mu(c)$ such that $\emptyset P_c s$, then $\mu$ is blocked by $c$. Moreover, if $sP_c \emptyset$ for all $s \in \mu(c)$, then $\mu$ is not blocked by $c$. Hence, individual rationality and acceptability are equivalent under Assumption 3. Moreover, Assumption 3 implies that if $cP_s \mu(s)$, $sP_c \emptyset$, and $|\mu(c)| < q_c$, then $(c, s)$ is a blocking pair for $\mu$. Similarly, if $sP_c s'$, $sP_c \emptyset$, $s' \in \mu(c)$, and $s \notin \mu(c)$, then $(c, s)$ is a blocking pair for $\mu$.

The existence of stable matchings has been widely studied in two-sided matching problems without externalities. For instance, in the college admission market, when the college preferences are responsive, then the set of stable matchings is nonempty (cf. Gale and Shapley, 1962; Roth, 1985). We prove a similar result for our environment.

**Proposition 3** Under Assumption 3, there exists at least one stable matching in any tuition-exchange market.

We prove this proposition by constructing an associated Gale–Shapley college-admissions market in which the set of Gale–Shapley–stable matchings is identical to the set of stable tuition–exchange matchings.

---

40In the earlier two–sided matching literature, stability a la Gale and Shapley (1962) has been the central solution concept. Technically, our model is similar to a two-sided matching model with externalities, i.e., agents have preferences over allocations rather than their matches. Sasaki and Toda (1996) introduced externalities in two-sided matching markets and various stability definitions. Pycia (2010) explores existence in two-sided matching when agents have preferences over peers and matches. The first model is quite general; however, their stability notion, which guarantees existence, requires a very conservative definition of blocking. The second model, on the other hand, does not cover externalities regarding the balancedness requirement. Pycia and Yenmez (2015) also focus on the existence of stable matching in a two-sided matching problem with externalities such that preferences satisfy a substitutes condition.

However, our model has major differences from standard externality models, which generally inspect peer effects or induce different stability definitions as a solution for the decentralized market. We introduce a new stability notion for the current model.
In Section 4, we show the incompatibility between individual rationality, nonwaste-
fulness, and balancedness under Assumption 1. Although Assumption 3 is stronger than
Assumption 1, the incompatibility result still holds under Assumption 3.

**Proposition 4** Under Assumption 3, there may not exist an individually rational and
nonwasteful matching that is also balanced.

Proposition 4 also shows that there exists no stable and balanced mechanism un-
der Assumption 3. One can then wonder whether there exists a stable mechanism that
performs better than all other stable mechanisms in terms of balancedness. We prove
otherwise.\(^{41}\)

**Proposition 5** Under Assumption 3, each college has the same net balance in all stable
matchings of a given market.

We also investigate what kinds of strategic decisions a tuition-exchange office in a
college would face in a quota-determination game if a stable outcome emerges in the mar-
ket. Here we explicitly make the aforementioned additional assumption about negative
net-balance aversion on college preferences.\(^{42}\)

**Assumption 4** (Negative Net-Balance Aversion) College \(c\) prefers \(\mu \in \mathcal{M}\), such that
\(b^c_\mu = 0\) and all \(s \in \mu(c)\) are acceptable, to all \(\nu \in \mathcal{M}\) with \(b^c_\nu < 0\).

In the quota-determination game, we fix \(C\), \(S\), \(\succ_C\), and \(\succeq\). Colleges are the players
of the game and each college’s strategy is setting its admission and eligibility quotas
under a simultaneous move, complete information setting. Without loss of generality, we
constrain the strategy space such that a reported admission quota is not less than the
reported eligibility quota. Given a true quota profile, denote the action set for \(c\) with
\(A_c\); then, it is \(A_c = \{(\hat{q}_c, \hat{e}_c) \in \mathbb{N}^2 | \hat{q}_c \geq \hat{e}_c \geq 0\}\). The outcome of the game is determined
by a stable mechanism (solution). In Theorem 10, by using the results of Proposition 6
below, we show that in any stable solution, if a college holds a negative net balance, then
the best response is only to decrease the eligibility quota. Proposition 6 also gives us a
comparative result regarding how the net balances of colleges change when they certify
one additional student and do not decrease their admission quotas.\(^{43}\)

\(^{41}\)We also inspect the structure of stable matchings, as our stability concept is novel, in Appendix F.
We show that there always exist college- and student-optimal stable matchings.

\(^{42}\)This assumption is used only in Theorem 10.

\(^{43}\)Weber (1997); Engelbrecht-Wiggans and Kahn (1998); Ausubel, Cramton, Pycia, Rostek, and
Weretka (2014) study demand reduction in auctions.
Proposition 6 Under Assumption 3, for fixed preferences \( \succeq \) and for any reported quota profiles \( \hat{q} \) and \( \hat{e} \), let \( \hat{\pi} \) and \( \tilde{\pi} \) be stable matchings for the induced markets \([\hat{q}, \hat{e}, \succeq]\) and \([(\hat{q}_c, \hat{q}_{c-}), (\hat{e}_c, \hat{e}_{c-}), \succeq]\), respectively, where \( \hat{q}_c \geq \hat{e}_c \), \( \hat{q}_c \geq \hat{q}_c \) and \( \hat{e}_c = \hat{e}_c + 1 \). Then \( b^\hat{\pi}_c \in \{b^\tilde{\pi}_c - 1, b^\tilde{\pi}_c \} \) if \( b^\tilde{\pi}_c < 0 \); and \( b^\hat{\pi}_c \in \{b^\tilde{\pi}_c - 1, b^\tilde{\pi}_c, \ldots, b^\tilde{\pi}_c + \hat{q}_c - \hat{q}_c \} \) if \( b^\tilde{\pi}_c \geq 0 \).

The proposition concludes that, when a college increases its eligibility quota by one without decreasing its admission quota, its overall net balance will decrease at most by one under any stable solution. Its net balance may increase only if it is a nonnegative net balance college to start with.\(^{44}\)

Theorem 10 Under Assumptions 3 and 4, for fixed preferences \( \succeq \) and for any reported quota profiles \( \hat{q} \) and \( \hat{e} \), if \( c \) has a negative net balance in a stable matching for market \([\hat{q}, \hat{e}, \succeq]\) where \( \hat{q}_c \geq \hat{e}_c \), then its best response in any stable solution is to set only lower \( \hat{e}_c \), but not higher; and in particular, there exist \( \hat{e}_c \leq \hat{e}_c \) such that college \( c \) has a zero–balance in every stable matching of the market \([\hat{q}, (\hat{e}_c, \hat{e}_{c-}), \succeq]\).

Theorem 10 shows that if \( c \) has a negative net balance then it certifies fewer students, which will eventually increase its balance.\(^{45}\) When \( c \) certifies fewer students it may cause another college \( c' \) to have a negative net balance. Then \( c' \) will have a negative net balance and will certify fewer students, too. In Theorem 11 below, we show this result.

Theorem 11 Under Assumption 3, for fixed preferences \( \succeq \) and for any reported quota profiles \( \hat{q} \) and \( \hat{e} \), if a college \( c \) is holding a negative net balance in a stable matching \( \mu \) for market \([\hat{q}, \hat{e}, \succeq]\) where \( \hat{q}_c \geq \hat{e}_c \) then \( b^\mu_{c'} \geq b^\mu_{c} \) where \( \mu' \) is any stable matching of market \([(q'_c, q_{c-}), (e'_c, e_{c-}), \succeq]\), \( q_c \geq q'_c \geq e'_c \) and \( e_c > e'_c \).

Theorems 10 and 11 do not conduct an equilibrium analysis in a quota-determination game. But they do point out that in a frictionless market, the colleges that will be likely to have a negative-balance will be conservative and will decrease their eligibility quotas for exports, which will further deteriorate the balances of other colleges.

Typically, no college fully withholds in practice, as there is often a minimum quota of participation in place. This is instituted most likely because of the reasons outlined above.

\(^{44}\)This is possible only if \( \hat{q}_c > \hat{q}_c \).

\(^{45}\)This result is in a similar vein as the results on college admissions where the DA mechanism is shown to be prone to admission quota manipulation of the colleges under responsive preferences, regardless of imbalance aversion (cf. Sönmez, 1997). However, Konishi and Üver (2006) show that the DA mechanism would be immune to quota manipulation, if preferences of colleges over incoming students were responsive and monotonic in number. On the other hand, even under this restriction of preferences over the incoming class, our result would imply all stable mechanisms are manipulable with quota reports for colleges with negative net balances if colleges have negative net-balance averse preferences. (See also Kojima and Pathak, 2009.)
Given that continued membership is an attractive benefit, often times, smaller colleges will announce that they will import and export at this minimum quota requirement (for example, it is 1 for TTEI), and will continue to be a member of the program without fully withdrawing from the system.

We conclude that under a new design for the tuition exchange market, there should be no room for quota underreporting by the colleges due to negative net-balance aversion, if possible. A fully centralized solution disregarding decentralized market stability seems to be inevitable, as stability is at odds with balancedness and has various other shortcomings regarding other incentives.

Moreover, we deem such a stability concept inappropriate for our purpose as the rights of students to participate in market activity depends on the permission of their colleges. Thus, we claim that balanced–efficiency and individual rationality are the most important features of a tuition–exchange outcome.

Appendix B Proofs

Proof of Propositions 1 and 4. Consider the following market. Let $C = \{a, b\}$ and for each $c \in C$ set $q_c = e_c = 1$. The set of students in each college is: $S_a = \{1\}$ and $S_b = \{2\}$. The associated strict preference relations of students over colleges are given as $P_1 : b P_1 c \emptyset$ and $P_2 : a P_2 c \emptyset$. Student 1 is not acceptable to $b$, i.e., $\emptyset P_b 1$, and $b$ prefers any matching in which 1 is not assigned to itself over the ones in which 1 is assigned to itself. Student 2 is acceptable to $a$ and $a$ prefers any matching with positive balance to the ones in which no student is assigned to itself. There is one nonwasteful matching that is not individually blocked: $\mu(1) = c \emptyset$ and $\mu(2) = a$. This matching is not balanced, as college $b$ has negative net balances under $\mu$.

Proof of Theorem 1. Consider an arbitrary market $[q, e, \succsim]$. Let $\pi$ be the matching selected by 2S-TTC in $[q, e, \succsim]$.

Individual Rationality: Since each $s \in S$ is assigned to a college better than $c \emptyset$, $s$ does not individually block $\pi$. Since all students in $\pi(c)$ are ranked above $\emptyset$ in $P_c$ for each $c \in C$, $\pi(c) R_c^c \tilde{S}$ for any $\tilde{S} \subseteq \pi(c)$. In any matching $\mu \in \mathcal{M}$ such that $\mu(s) = \pi(s)$ for all $s \in S \setminus \pi(c)$ and $\mu(c) \subset \pi(c)$, $c \in C$ has a nonpositive net balance. Hence, $\pi$ is not individually blocked by $c$.

Acceptability: Students will be assigned to the null college, $c \emptyset$, whenever they point to it, and, hence, they will never need to point to an unacceptable college. Moreover, a student cannot point to a college that considers her unacceptable. Therefore, the students ranked below $\emptyset$ in $P_c$ cannot be assigned to $c$. Thus, the 2S-TTC is acceptable.
Respect for Internal Priorities: Suppose, contrary to the claim, that 2S-TTC does not respect internal priorities. Then, there exists \( s \in S_c \) who is assigned to a college by 2S-TTC in \([q, e, \succeq]\), but not in \([(\tilde{q}_c, q_{-c}), (\tilde{e}_c, e_{-c}), \succeq]\) where \( q_c > 0 \) and \( e_c > e_c \). Note that \( \tilde{q}_c \geq q_c \) and \( \tilde{e}_c > e_c \). We use a variation of the 2S-TTC in which only the students with the highest internal priority at their home colleges point to a college in \( C \) each round. Since only the top-priority students and students pointing to \( c_0 \) can form a cycle in each round under both versions of 2S-TTC, they will select the same outcome. Let \( S(k) \) and \( \tilde{S}(k) \) be the set of students assigned in Round \( k \) of 2S-TTC applied to the problems \([q, e, \succeq]\) and \([(\tilde{q}_c, q_{-c}), (\tilde{e}_c, e_{-c}), \succeq]\), respectively. In both problems, the same set of agents will be active in the first round. Since we consider the same preference profile, \( S(1) = \tilde{S}(1) \). Then, if \( s \in S(1) \), we are done. If not, consider the second round. Since the same set of students is removed with their assignments and \( s \notin S(1) \), the set of active students and the remaining colleges in the second round of 2S-TTC applied to the problems will be the same. Moreover, students will be pointing to the same colleges in both problems. Hence, \( S(2) = \tilde{S}(2) \). Then, if \( s \in S(2) \), we are done. If not, we can repeat the same steps and show that \( s \) will be assigned in the matching selected by the 2S-TTC in market \([(\tilde{q}_c, q_{-c}), (\tilde{e}_c, e_{-c}), \succeq]\).

Balanced-efficiency: Since the matching selected by the 2S-TTC consists of trading cycles in which students and their assignments form unique cycles, its outcome is balanced by Remark 1. Since 2S-TTC is acceptable, \( \pi \) is also acceptable. Let \( S(k) \) be the set of students assigned in Round \( k \) of 2S-TTC. We will prove that \( \pi \) is balanced-efficient in two parts.

Part I: We first prove that \( \pi \) cannot be Pareto dominated by another acceptable balanced matching. If \( s \in S(1) \), then \( \pi(s) \in C \cup c_0 \) is the highest ranked college in her preference list that considers her acceptable. That is, no agent \( s \in S(1) \) can be assigned to a better college considering her acceptable. If there exists \( \nu \in \mathcal{M} \) such that \( \nu \succeq_s \pi \), then \( \nu(s) \) considers \( s \) unacceptable. That is, \( \pi \) cannot be Pareto dominated by another \( \nu \) in which at least one student in \( S(1) \) is better off under \( \nu \), and all students are assigned to a college that considers them acceptable.

If a student \( s \in S(2) \) is not assigned to a more preferred \( c \in C \) that considers her acceptable, then \( c \) should either fill its quota in Round 1 by another \( s' \in S \), or \( e_c = 1 \) and the only eligible student \( \tilde{s} \in E_c \) is assigned to \( c_0 \). For the first case, because \( s' \) is assigned in Round 1, \( \pi(s') = c \) is her favorite college among the ones considering her acceptable. That is, in any acceptable matching \( \nu \in \mathcal{M} \) in which \( s \) is assigned to \( \pi(s') \), \( s' \) will be made worse off. For the second case, \( \tilde{s} \) needs to be assigned to a college in order for \( s \) to be assigned to \( c \). Otherwise, balancedness will be violated. This will violate acceptability,
since \( \tilde{s} \) considers all colleges considering her acceptable as unacceptable. Hence, \( \pi \) cannot be Pareto dominated by another balanced and acceptable matching \( \nu \) in which at least one student in \( S(2) \) is better off under \( \nu \).

We similarly show the same for all other rounds of the 2S-TTC. Thus, in a balanced matching no student can be assigned to a better college without harming any other student among the colleges that consider her acceptable. Hence, no college can be made better off without harming another college either, if we focus on matchings that are acceptable and balanced.

**Part II:** Next we show that there does not exist an unacceptable balanced matching that Pareto dominates \( \pi \). To the contrary of the claim, suppose there exists an unacceptable balanced matching \( \nu \) that Pareto dominates \( \pi \). Then each \( i \in C \cup S \) weakly prefers \( \nu \) to \( \pi \), and at least one agent \( j \in C \cup S \) strictly prefers \( \nu \) to \( \pi \). Due to the acceptability of the 2S-TTC, every student weakly prefers her assignment in \( \pi \) to \( c_0 \). Therefore, every assigned student in \( \pi \) is also assigned to an acceptable college under \( \nu \). Thus, due to the balancedness of both \( \pi \) and \( \nu \), \( |\nu(c)| \geq |\pi(c)| \) for all \( c \in C \). As \( \nu \) is unacceptable, there exists some \( c_0 \in C \) such that \( s_0 \in \nu(c_0) \) is unacceptable for \( c_0 \). As \( \nu \succeq_{c_0} \pi \), there should be at least one student \( s_1 \in \nu(c_0) \setminus \pi(c_0) \) such that \( s_1 \) is acceptable for \( c_0 \) by Assumption 1. We consider two cases regarding \( \pi(s_1) \):

1. First, suppose \( \pi(s_1) = c_0 \). Denote the home college of \( s_1 \) by \( c_1 \). Hence, \( |\nu(c_1)| > |\pi(c_1)| \) by balancedness of \( \nu \) and \( \pi \). By Assumption 1, \( \nu(c_1) P^*_{c_1} \pi(c_1) \), and there exists a student \( s_2 \in \nu(c_1) \setminus \pi(c_1) \) such that \( s_2 \) is acceptable for \( c_1 \) and \( \nu(s_2) P_{s_2} \pi(s_2) \).

2. Next, suppose \( \pi(s_1) \in C \). Denote \( \pi(s_1) \) by \( c_1 \). As \( |\nu(c_1)| \geq |\pi(c_1)| \), there exists \( s_2 \in \nu(c_1) \setminus \pi(c_1) \), and \( s_2 \) is acceptable for \( c_1 \) by Assumption 1. We also have \( \nu(s_2) P_{s_2} \pi(s_2) \).

We continue with \( s_2 \) and \( \pi(s_2) \), similarly construct \( c_2 \), and then \( s_3 \). As we continue, by finiteness, we should encounter the same student \( s_k = s_\ell \) for some \( k > \ell \), that is, we’ve encountered her before in the construction. Consider the students \( s_\ell + 1, s_\ell + 2, \ldots, s_k \). Let \( s_{k'} \) be the student who is assigned in the earliest round of the 2S-TTC in this list. By definition, she points to \( \pi(s_{k'}) \). However, she prefers \( c_{k'-1} \) to her assignment, and she is acceptable for \( c_{k'-1} \). Moreover, we know that \( c_{k'-1} \) has not been removed yet from the algorithm, because if \( c_{k'-1} \) was constructed in Case 1 above, then \( q_{c_{k'-1}} > |\pi(c_{k'-1})| \) and \( s_{k'-1} \in S_{c_{k'-1}} \) is still not removed, and if \( c_{k'-1} \) was constructed in Case 2 above, then \( s_{k'-1} \in \pi(c_{k'-1}) \) is still not removed. Therefore, \( s_{k'} \) should have pointed to \( c_{k'-1} \) in the 2S-TTC in that round. This is a contradiction to \( \nu \) Pareto dominating \( \pi \).

**Proof of Theorem 2.** Suppose that there does exist such a mechanism. Denote it by \( \psi \). We use different problems to show our result.

**Case 1:** Let \( C = \{a, b, c\} \) and \( S_a = \{1, 2\} \), \( S_b = \{3\} \), and \( S_c = \{4\} \). Let \( q =
Let $\succeq$ be the student preference profile with associated rankings over colleges $P_1 : bP_1 cP_1 \emptyset$, $P_2 : cP_2 \emptyset$, $P_3 : aP_3 \emptyset$, and $P_4 : aP_4 \emptyset$. Let $\succeq_C$ be the college preference profile with associated rankings over students $P_a : 3P_a 4P_a \emptyset$, $P_b : 1P_b \emptyset$, and $P_c : 1P_c 2P_c \emptyset$. We assume that $\succeq_C$ satisfies Assumption 1. There are two balanced–efficient and individually rational matchings: $\mu_1 = (4 \emptyset 1) \land \mu_2 = (\{3, 4\} 1 2)$. If $\psi$ selects $\mu_1$, then $a$ can manipulate $\psi$ by submitting $\succeq_a$ where $P_a^1 : 3P_a^1 \emptyset$ and any acceptable matching is preferred to $\mu_1$. Note that, $\succeq_a$ satisfies Assumption 1. Then the only individually rational and balanced–efficient matching is $\mu_3 = (a b c)$. Therefore, $\psi[q, e, \succeq] = \mu_2$.

**Case 2:** We consider the same example with a slight change in $a$’s preferences. Let $\succeq_a^2$ be $a$’s preferences over the matchings with associated ranking $P_a^2 : 4P_a^2 3P_a^2 \emptyset$. We assume that $\succeq_a^2$ satisfies Assumption 1. In this case, $\mu_1$ and $\mu_2$ are the only two balanced–efficient and individually rational matchings.

If $\psi$ selects $\mu_1$, then $a$ can manipulate $\psi$ by submitting $\succeq_a$. Then we will be in Case 1 and $\mu_2$ will be selected, which makes $a$ better off. Therefore, $\psi[q, e, (\succeq_a^2, \succeq_{-a})] = \mu_2$.

**Case 3:** Now consider the case where colleges report the preferences $\succeq_3$ where $\succeq_a^3 = \succeq_a^2$, $\succeq_b^3 = \succeq_b$, $P_c^3 : 1P_c^3 \emptyset$ is the associated ranking with $\succeq_c^3$ and any acceptable matching is preferred to $\mu_2$ under $\succeq_3$. Note that, $\succeq_3$ satisfies Assumption 1. Then there are two individually rational and balanced–efficient matchings : $\mu_4 = (a b c)$ and $\mu_5 = (4 \emptyset 1)$. If $\psi$ selects $\mu_4$, then in Case 2 $c$ can manipulate $\psi$ by reporting $\succeq_c^3$. Therefore, $\psi[q, e, \succeq_3] = \mu_5$.

**Case 4:** Now consider the case where colleges report the following preferences $\succeq_4$ where $\succeq_a^4 = \succeq_b$, $\succeq_c^4 = \succeq_c$, $P_a^4 : 4P_a^4 \emptyset$ is the associated ranking with $\succeq_a^4$ and any acceptable matching is preferred to $\mu_5$ under $\succeq_4$. Note that, $\succeq_4$ satisfies Assumption 1. There is a unique balanced–efficient and individually rational matching: $\mu_4$. In Case 3, $a$ can manipulate $\psi$ by reporting $\succeq_a^1$; then we will be in Case 4 and $a$ will be better off with respect to Case 3 preferences.

Therefore, there does not exist a balanced–efficient, individually rational mechanism that is immune to preference manipulation by colleges.

**Proof of Theorem 3.** Consider the preference relations of each student who ranks as acceptable only those colleges that find her acceptable. If we consider only these preferences as possible preferences to choose from for each student, we see that the 2S-
TTC is group strategy-proof for students, as Pápai (cf. 2000) showed that the TTC is group strategy-proof. In the 2S-TTC, observe that students are indifferent among reporting preference relations that rank the colleges finding themselves as acceptable in the same relative order. Thus, the 2S-TTC is group strategy-proof for students.

The following Lemma is used in proving Theorem 4:

**Lemma 1** Let $\pi$ and $\tilde{\pi}$ be the outcome of 2S-TTC in $[q, e, \succsim]$ and $[(\tilde{q}_c, q_{-c}), (\tilde{e}_c, e_{-c}), \succsim]$ where $\tilde{q}_c \leq q_c$ and $\tilde{e}_c \leq e_c$ for some $c \in C$, respectively. Then, $M^\pi_c \subseteq M_e^\pi$, $\tilde{\pi}^{-1}(c) \subseteq \pi^{-1}(c)$ and $X_c^\pi \subseteq X_c^\pi$.

**Proof.** If $\tilde{q}_c = q_c$ and $\tilde{e}_c = e_c$, then $\tilde{\pi} = \pi$. Hence, we have three remaining cases to consider:

**Case 1:** $\tilde{q}_c = q_c$ and $\tilde{e}_c < e_c$. We consider the case in which one more student is certified by $c$, i.e., $\tilde{e}_c + 1 = e_c$. Denote the student added to the eligible set by $s$. Let $s' \in S_c$ and $r_c(s') = r_c(s) - 1$. Consider the execution of the 2S-TTC for this new market. If $\tilde{q}_c$ students are assigned to $c$ before $s'$’s turn, then $c$ will be removed, and certifying one more student will not affect the set of students exported and imported by $c$. Now consider the case in which less than $\tilde{q}_c$ students are assigned to $c$ before $s'$’s turn. Denote the intermediate matching that we have just after $s'$ is processed by $\nu$. Since $c$ is removed just after $s'$ is processed in $[(\tilde{q}_c, q_{-c}), (\tilde{e}_c, e_{-c}), \succsim]$, $M_c^\pi = M_c^\nu$, $\tilde{\pi}^{-1}(c) = \nu^{-1}(c)$, and $X_c^\pi = X_c^\nu$. If $s$ is assigned to a college $c' \in C \setminus c$, $c$ will import one more acceptable student. Denote that matching by $\mu$. Then, we have $M_c^\pi = M_c^\nu \subseteq M_c^\mu$, $\tilde{\pi}^{-1}(c) = \nu^{-1}(c) \subseteq \mu^{-1}(c)$, and $X_c^\pi = X_c^\nu \subseteq X_c^\mu$. If $s$ is assigned to the $c_0$ or $c$, then $c$ will have the same import and export set and for the latter case we have $\tilde{\pi}^{-1}(c) = \nu^{-1}(c) \subseteq \mu^{-1}(c)$. If we keep certifying all $e_c - \tilde{e}_c$ students one at a time, we will have $M_c^\pi \subseteq M_c^\pi$, $\tilde{\pi}^{-1}(c) \subseteq \mu^{-1}(c)$ and $X_c^\pi \subseteq X_c^\pi$, where $\pi$ is the outcome of the 2S-TTC in $[q, e, \succsim]$.

**Case 2:** $\tilde{q}_c < q_c$ and $\tilde{e}_c = e_c$. Let $\pi$ and $\nu$ be the outcomes of the 2S-TTC in $[q, e, \succsim]$ and $[(\tilde{q}_c, q_{-c}), e, \succsim]$, respectively. If $|\nu^{-1}(c)| < \tilde{q}_c$ then the 2S-TTC will select $\nu$ when $c$ reports either $\tilde{q}_c$ or $q_c$. That is, $\pi = \nu$. If $|\nu^{-1}(c)| = \tilde{q}_c$ and all eligible students of $c$ are considered in $[(\tilde{q}_c, q_{-c}), e, \succsim]$ when it is removed, then it will not make a difference if $c$ reports either $\tilde{q}_c$ or $q_c$. If $|\nu^{-1}(c)| = \tilde{q}_c$ and $c$ is removed before all its eligible students are considered, then one more student $s \in S_c$ might be considered when $c$ reports $q_c$. As in the previous case, $c$ may import and export at least one more student. At the end, we get $M_c^\nu \subseteq M_c^\pi$, $\nu^{-1}(c) \subseteq \pi^{-1}(c)$ and $X_c^\nu \subseteq X_c^\pi$.

**Case 3:** $\tilde{q}_c < q_c$ and $\tilde{e}_c < e_c$. Let $\mu$ be the outcome of the 2S-TTC in $[q, (\tilde{e}_c, e_{-c}), \succsim]$. Then, we have $M_c^\pi \subseteq M_c^\mu \subseteq M_c^\pi$, $\tilde{\pi}^{-1}(c) \subseteq \mu^{-1}(c) \subseteq \pi^{-1}(c)$ and $X_c^\pi \subseteq X_c^\mu \subseteq X_c^\pi$, where the first and second subset relations come from invoking Case 1 and Case 2, respectively.
Proof of Theorem 4. We prove a stronger version of Theorem 4: Under the 2S-TTC, suppose that preference profiles are fixed for colleges such that no college reports an unacceptable student as acceptable in its preference report. In the induced quota-reporting game, under Assumption 1, it is a weakly dominant strategy for any $c \in C$ to certify all its students and to reveal its true admission quota.

Take a market $[q, e, \succeq]$ and a college $c$. Suppose that preference reports are fixed such that $c$ does not report any unacceptable students as acceptable in these reports. We have two cases to consider for possible quota manipulations by $c$:

Case 1: $c$ reports $(\tilde{q}_c, \tilde{e}_c)$ where $\tilde{q}_c \leq q_c$ and $\tilde{e}_c \leq |S_c|$: In Lemma 1 we have shown that when $c$ reports its admission and eligibility quotas as higher, the set of students imported by $c$ (weakly) expands. By Assumption 1, reporting $(\tilde{q}_c, \tilde{e}_c)$ is weakly dominated by reporting the true admission quota and certifying all students.

Case 2: $c$ reports $\tilde{q}_c$ where $\tilde{q}_c > q_c$: This strategy is weakly dominated by reporting its true admission quota $q_c$. We prove this as follows: Let $\nu$ and $\mu$ be the matchings that the 2S-TTC mechanism selects when $c$ reports $\tilde{q}_c$ and $q_c$, respectively. If $|\nu^{-1}(c)| \leq q_c$, then $M^{\nu}_c = M^{\mu}_c$, $\nu^{-1}(c) = \mu^{-1}(c)$, and $X_{\nu}^e = X_{\mu}^e$; thus, it is indifferent between the two matchings. However, if $|\nu^{-1}(c)| > q_c$, among the balanced matchings by Assumption 1, colleges’ preferences depend on the preferences on admitted students, which are only responsive up to the true admission quota, and $\mu$ is individually rational, so it prefers $\mu$ to $\nu$.

Proof of Proposition 2. The 2S-TTC mechanism takes into account only the set of acceptable students based on the submitted preferences of colleges over the matchings. Hence, for any two different preference profiles with the same set of acceptable students, the 2S-TTC selects the same outcome.

Proof of Theorem 5. We use a variant of the 2S-TTC in which we select only one cycle in one round. If there is more than one cycle, then the selection is done randomly. Let $S(k)$ be the set of students removed in Round $k$. Suppose the theorem does not hold. Let $\psi$ be the mechanism satisfying all four axioms, and select a different matching for some problem $[q, e, \succeq]$. Denote the outcome of 2S-TTC for $[q, e, \succeq]$ by $\mu$. In the rest of the proof, we work on students’ preferences over colleges, $P_S$, instead of matchings, $\succeq_S$.

We first prove the following claim:

Claim: If there exists a student in $S(k)$ who prefers her assignment in $\psi[q, e, \succeq]$ to the one in $\mu$, then there exists another student in $\bigcup_{k'=1}^{k-1} S(k')$ who prefers her assignment in $\mu$ to the one in $\psi[q, e, \succeq]$.

Proof of Claim: We use induction in our proof. Consider the students in $S(1)$.

\footnote{We take $\bigcup_{k'=1}^{0} S(k') = \emptyset$.}
First consider the case in which $S(1)$ is a singleton and the student in $S(1)$ is assigned to $c_0$. Any college that she prefers to $c_0$ considers her unacceptable. If she prefers her assignment under $\psi$ to $c_0$, then she is assigned to a college that considers her unacceptable by $\psi$. Therefore, $\psi$ is not acceptable. If she prefers $c_0$ to her assignment under $\psi$, then $\psi$ is not acceptable. Then any acceptable mechanism will assign her to $c_0$. If $S(1)$ is not a singleton or $S(1)$ is singleton and the student in $S(1)$ is assigned to her own college, then each student in $S(1)$ is assigned to the best college that considers her as acceptable, and she prefers her assignment in $\mu$ to $c_0$. If $s \in S(1)$ prefers her assignment in $\psi[q,e,\preceq] \to \mu(s)$, then $\psi$ is not acceptable. Hence, each student in $S(1)$ weakly prefers her assignment in $\mu$.

In the inductive step, assume that for all Rounds $1,\ldots,k-1$, for some $k > 1$, the claim is correct. Consider Round $k$. If there exists a student $s \in S(k)$ such that $c = \psi[q,e,\preceq](s)P_s\mu(s)$, then either $c$ considers $s$ acceptable and its seats are filled in Rounds $1,\ldots,k-1$ of 2S-TTC, or $s$ is unacceptable for $c$. In the latter case, $\psi$ is not acceptable. Consider the former case. First, note that $c \neq c_0$ since $q_{c_0} = |S|$. Let $s'$ be assigned to $c$ under $\mu$ in Round $k' \leq k-1$ but not under $\psi[q,e,\preceq]$, as $s$ is assigned instead of her. If she prefers $c$ to $\psi[q,e,\preceq](s')$, then we are done. If she does not, $k' > 1$, and by the inductive step, there exists a student $s'' \in S(k'')$ for some $k'' < k' \leq k-1$ who prefers $\mu(s'') \to q,e,\preceq(s'')$. \hfill \diamond

Now we are ready to prove the theorem. By the Claim and the observation above, as $\mu \neq \psi[q,e,\preceq]$, there exists a student $s$ and some round $k > 1$ such that $s \in S(k)$ prefers $\mu(s) \to q,e,\preceq(s)$, and $\mu(s') = \psi[q,e,\preceq](s')$ for all $s' \in \cup_{k'=1}^{k-1}S(k')$.

We will construct our proof in three steps. Assign to each round of the 2S-TTC mechanism a counter and set it as $\text{Counter}(k') = |S(k')| - 1$ for all rounds $k'$.

**Step 1:** Construct a preference profile $\widetilde{\preceq}$ with associated ranking $\widehat{P}$ as follows: Let student $s \in S_c$ rank only $\mu(s)$ as acceptable in $\widehat{P}_s$ and $\widetilde{\preceq}_j = \preceq_j$ for all $j \in [(C \cup S) \setminus s]$. The 2S-TTC will select $\mu$ for $[q,e,\widetilde{\preceq}]$. Since $\psi$ is student strategy-proof and acceptable, $\psi[q,e,\widehat{\preceq}](s) = c_0$.

Then, we check whether the assignments of students in $\cup_{k'=1}^{k-1}S(k')$ are the same in $\psi[q,e,\widehat{\preceq}]$ and $\mu$. If not, then for some $\tilde{k} < k$, there exists a student $\tilde{s} \in S(\tilde{k})$ preferring $\mu(\tilde{s})$ to $\psi[q,e,\widehat{\preceq}](\tilde{s})$ and each student in $\cup_{k'=1}^{k-1}S(k')$ gets the same college in $\mu$ and $\psi[q,e,\widehat{\preceq}]$. Then we repeat Step 1 by taking $\widetilde{\preceq} := \widehat{\preceq}$, $s := \tilde{s}$, and $k := \tilde{k}$.

This repetition will end by the finiteness of rounds and the fact that $\cup_{k'=1}^{0}S(k') = \emptyset$. When all students in $\cup_{k'=1}^{k-1}S(k')$ get the same college in $\mu$ and $\psi[q,e,\widehat{\preceq}]$, then we proceed to Step 2.

**Step 2:** In Step 1, we have shown that $s$ prefers $\mu(s)$ to $\psi[q,e,\widehat{\preceq}](s) = c_0$. Suppose
\(c\) is the home college of \(s\). Set a new eligibility quota \(\tilde{e}_c\) equal to the rank of student \(s\) in \(c\)'s internal priority order, that is, \(\tilde{e}_c = r_c(s)\), and let \(\tilde{e}_{\sim c} = e_{\sim c}\). In \([q, \tilde{e}, \tilde{c}]\), the 2S-TTC assigns all students in \(\cup_{k'=1}^{k-1} S(k')\) to the same college as in \(\mu\). \(\psi[q, \tilde{e}, \tilde{c}] \equiv c_0\) since \(\psi\) respects internal priorities and we weakly decreased \(c\)'s eligibility quota. We check whether the assignments of students in \(\cup_{k'=1}^{k-1} S(k')\) are the same in both \(\psi[q, \tilde{e}, \tilde{c}]\), and \(\mu\). If not, then by the Claim, there should exist \(\tilde{s} \in S(\tilde{k})\) preferring \(\mu(\tilde{s})\) to \(\psi[q, \tilde{e}, \tilde{c}]\), and each student in \(\cup_{k'=1}^{k-1} S(k')\) gets the same college in \(\mu\) and \(\psi[q, \tilde{e}, \tilde{c}]\) where \(\tilde{k} < k\); then we restart from Step 1 by taking \(\tilde{\zeta} := \tilde{\zeta}, s := \tilde{s}, k := \tilde{k}\), and \(e := \tilde{e}\).

Eventually, by the finiteness of the rounds of the 2S-TTC and as we reduce the round \(k\) in each iteration, we reach the point in our proof such that students in \(\cup_{k'=1}^{k-1} S(k')\) get the same college in \(\mu\) and \(\psi[q, \tilde{e}, \tilde{c}]\).

Observe that \(s\) is the last remaining eligible student of \(c\) in Round \(k\) of 2S-TTC for \([q, \tilde{e}, \tilde{c}]\) by the choice of \(\tilde{e}_c = r_c(s)\). If \(S(k)\) is singleton, then \(\mu(s)\) is the home college of \(s\). Suppose \(|S(k)| > 1\). Since for all \(s'' \in \cup_{k'=1}^{k-1} S(k')\), \(\mu(s'') = \psi[q, \tilde{e}, \tilde{c}]\) and \(\mu(s')\) \(\bar{P}_s\) \(\psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\), \(s' \in S(k) \cap \mu(c)\) will be assigned to a different college in \(\psi[q, \tilde{e}, \tilde{c}]\) than \(c\). Otherwise, \(\psi\) is not balanced. As for all \(s'' \in \cup_{k'=1}^{k-1} S(k')\), \(\mu(s'') = \psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\), and \(s'\) points to the best available college that finds her acceptable in Round \(k\), \(s' = \mu(s')\) \(\bar{P}_s\) \(\psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\). We decrease \(\text{Counter}(k)\) by 1. If \(\text{Counter}(k) > 0\) then we turn back to Step 1 by taking \(\tilde{\zeta} := \tilde{\zeta}\) and \(s := s'\); otherwise we continue with Step 3. Note that eventually we will find a Step \(K\) such that \(\text{Counter}(K) = 0\), because we weakly decrease all counters and decrease one counter by 1 in each iteration of Step 2.

**Step 3**: By the construction above, each \(\tilde{s} \in S(k)\) ranks only \(\mu(\tilde{s})\) as acceptable in \(\bar{P}_s\) and she is the last certified student by her home college in \([q, \tilde{e}, \tilde{c}]\). If \(|S(k)| = 1\), then \(\mu(s)\) is the home college of \(s\) and \(\psi[q, \tilde{e}, \tilde{c}]\) is Pareto dominated by the matching in which each student other than \(s\) is assigned her assignment under \(\psi[q, \tilde{e}, \tilde{c}]\) and \(s\) is assigned to \(\mu(s)\). Therefore, if \(|S(k)| = 1\), then \(\psi[q, \tilde{e}, \tilde{c}]\) cannot be balanced efficient. Now, suppose \(|S(k)| > 1\). In Step 2, we showed that there exist at least 2 students \(s_1(=s\text{ in Step 2}), s_2(=s'\text{ in Step 2})\) in \(S(k)\) who are not assigned to \(\mu(s_1)\) and \(\mu(s_2) = c_1\) (= \(c\) in Step 2), respectively, in \(\psi[q, \tilde{e}, \tilde{c}]\), where \(c_1\) is the home college of \(s_1\). Then, they are assigned to \(c_0\) in \(\psi[q, \tilde{e}, \tilde{c}]\), by the acceptability of \(\psi\). Recall that in the 2S-TTC for \([q, \tilde{e}, \tilde{c}]\), each student certified by the home colleges of \(s_1\) and \(s_2\) – colleges \(c_1\) and \(c_2\), respectively – other than \(s_1\) and \(s_2\) is removed in a round earlier than \(k\). Suppose for \(s_3 \in S(k), \mu(s_3) = c_2\). Since \(\psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\), for all \(\tilde{s} \in \bigcup_{k'=1}^{k-1} S(k')\), \(\psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\) (by Step 2), and \(\psi\) is balanced, \(s_3\) cannot be assigned to \(c_2\) in \(\psi[q, \tilde{e}, \tilde{c}]\), and hence, \(\psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\). We continue similarly with \(s_3\) and the home college of \(s_3\), say college \(c_3\), eventually showing that for all \(\tilde{s} \in S(k), \psi[q, \tilde{e}, \tilde{c}]\)\(\equiv c_0\). Recall that students in
$S(k)$ had formed a trading cycle in which each agent in the cycle was assigned in $\mu$ the home college of the next student in the cycle. Thus, $\psi[q, \tilde{e}, \geq]$ is Pareto dominated by the balanced matching $\nu$ obtained as $\nu(\bar{s}) = \psi[q, \tilde{e}, \geq](\bar{s})$ for all $\bar{s} \in S \setminus S(k)$ and $\nu(\bar{s}) = \mu(\bar{s})$ for all $\bar{s} \in S(k)$; that is, $\nu$ is obtained from $\psi[q, \tilde{e}, \geq]$ by students in $S(k)$ trading their assignments with each other to get their assignments in $\mu$. This is because each college in the cycle of Round $k$ gets one acceptable student more and each student weakly prefers $\mu$ to $\psi[q, \tilde{e}, \geq]$. This contradicts the balanced--efficiency of $\psi$. Hence, $\psi[q, e, \geq] = \mu$, i.e., $\psi$ is equivalent to 2S-TTC.

**Proof of Theorem 6.** Let $\psi$ satisfy all conditions and be strategy-proof for students. Then, consider the following example. There are 3 colleges $C = \{a, b, c\}$ with $q = e = (2, 1, 1)$. Let $S_a = \{1, 2\}$, $S_b = \{3\}$, $S_c = \{4\}$, and each student be acceptable to each college and the college preference profile satisfy Assumption 1. The internal priority order of a and student preference profiles are given as: $1, b, c, 4$.

The 2S-TTC selects $\mu = (a \ b \ c \ 1 \ 2)$. $\psi$ will also select $\mu$, since any other matching in which all students are assigned is individually irrational (and unacceptable).

If student 4 reports $\succ_4'$ with associated ranking $P'_4 : bP'_4 c0, cP'_4 b0, aP'3 c0, bP'_4 aP'4 c0$. Then 2S-TTC will select $\mu' = (a \ b \ c \ 3 \ 1 \ 0)$. The only balanced and individually rational (acceptable) matching in which more than two students are assigned is $\mu'' = (a \ b \ c \ 3 \ 4 \ 2)$. Therefore, the outcome of $\psi$ when 4 reports $\succ_4'$ is $\mu''$. Hence, 4 can manipulate $\psi$.

**Proof of Theorem 7.** We first prove the strategy-proofness of 2S-TTTC for students. Consider a tuition exchange problem $[q, e, \geq]$ and tolerance profile $t = (\ell_c, u_c)_{c \in C}$. We use a variation of 2S-TTTC in which only the student with the highest internal priority among the remaining students at some college points to a college other than $c_0$ in each round. Let $\mu$ be the matching selected by 2S-TTTC under truth-telling. Let $k > 0$ be the first round that we cannot locate a cycle. Note that in Round $k$ either there exists a chain, which may or not respect tolerance interval, or the mechanism terminates. Student $s$ assigned in Round $k' < k$ (under truth-telling) cannot affect the assignments done in earlier rounds. Before Round $k'$, all the colleges considering $s$ acceptable that $s$ prefers to $\mu(s)$ should have been removed since each student, who is allowed to point, points to the most preferred college among the remaining ones. If $s$ forms a cycle by misreporting in Round $k'' < k'$, then she should have pointed to a worse college than $\mu(s)$. Therefore, student $s$ cannot get a better college by misreporting.

Now consider Round $k$. If Round $k$ is the termination round, then we are done. Otherwise, firstly assume that we have a chain respecting tolerance interval. As we
mentioned above, any active student in Round \( k \) cannot affect the assignments done in earlier rounds. Then consider the student pointed to by the tail college of the chain. This student will be assigned in this round no matter which college she points to. Therefore she will point to the most preferred college considering her acceptable among the remaining ones. The next students in the chain will do so as well. The other active students in this round cannot affect the assignment of students in the chain without hurting themselves.

Now consider the case where we don’t have a chain respecting tolerance interval. That is, each exporting college \( c \) has a balance of \( \ell_c \). Then we will remove all the non-exporting colleges and 2S-TTTC reduces to the 2S-TTC mechanism. It is easy to see that we will not have chains in the future rounds also.

Let \( k'' > k \) be the first round after Round \( k \) that we cannot locate a cycle. Note that such a round might not exist if \( k \) is the termination round. Then we can apply the same reasoning that we used for rounds before \( k \) and show that all agents assigned in Round \( \tilde{k} \) such that \( k < \tilde{k} < k'' \) cannot be better off by misreporting. This is also true for Round \( k'' \).

Next we prove 2S-TTTC’s outcome cannot be Pareto dominated by an acceptable matching \( \nu \) satisfying tolerable balance. Denote the outcome of the 2S-TTTC mechanism with \( \mu \). Let \( k \geq 1 \) be the first round that we cannot locate a cycle. We consider the variant that we described above. As described above, either \( k \) is the termination round or there exist chain in Round \( k \). Note that, whenever \( S \neq \emptyset \) 2S-TTTC cannot terminate in Round 1. In the first round, each student is pointing to her most preferred college among the ones considering her acceptable. If a student is assigned in this round, then she should get the same college under \( \nu \). Now consider students assigned in Round \( k' < k \) when \( k > 1 \). All the colleges that a student preferred to her assignment that consider her acceptable should have been removed in an earlier round, and we cannot make that student better off without hurting another student assigned in an earlier round. Note that all colleges removed in Round \( k' < k \) fulfill either certification or the admission quota.

If \( k \) is the termination round, we are done. Otherwise, we consider the students assigned in Round \( k \). First, consider the case where there exists a chain not violating the tolerance interval. All of the students in that chain are assigned to a college that they prefer most among the remaining ones that consider them acceptable. They cannot be made better off without making some students assigned in the earlier rounds worse off. If there does not exist a chain respecting tolerance interval, then 2S-TTTC reduces to the 2S-TTC mechanism. If college \( c \) is removed because of either \( b_c^U = u_c \) or \( b_c^L = \ell_c \), then we cannot assign more students to \( c \) in \( \nu \).

Let \( k'' > k \) be the first round after Round \( k \) that we cannot locate a cycle. Note that
such a round might not exist if $k$ is the termination round. Then we can apply the same reasoning that we have used for rounds before $k$ and show that all agents assigned in Round $\hat{k}$ such that $k < \hat{k} < k''$ cannot be better off by misreporting. This is also true for Round $k''$.

Every student assigned to a college should be assigned the same college in $\nu$. If we assign fewer students, then at least one student would be better off under $\mu$ compared to $\nu$. If we assign more students in $\nu$ then either feasibility or the tolerance conditions are violated.

**Proof of Theorem 8.** We refer to the proof of Theorem 1.

**Proof of Theorem 9.** Recall that the 2S-TTC mechanism in the general domain can be run by using the set of colleges’ acceptable students, and that while proving the properties of 2S-TTC we consider only these sets of acceptable students. Hence, we can use the same proofs for the 2S-TTC in the general domain here. We refer to the proof of Theorem 1 and Theorem 3 for balance–efficiency, acceptability, individual rationality, strategy-proofness for students, and respecting internal priorities. We refer to the proof of Theorem 5 for uniqueness.

**Immunity to Preference Manipulation by Colleges:** Under Assumption 2, firms are indifferent between any balanced and acceptable matching that fills their quota. Since the 2S-TTC mechanism selects a balanced and acceptable matching that fills all firms’ quotas, firms cannot be better off by manipulating their preferences over the matchings and reporting quotas different from their true quotas and not certifying all its students.

**Stability:** Denote the outcome of the 2S-TTC by $\mu$. Recall that $q_c = |S_c|$ for all $c \in C$, all workers consider their current jobs acceptable, all firms consider their current workers acceptable, and workers who are not certified remain at their current jobs. Hence, $|\mu(c)| = q_c$ for all $c \in C$. Since under $\mu$ all firms’ quotas are filled, $\mu$ is nonwasteful. Since all employees in $\mu(c)$ are acceptable, replacing one of the employees in $\mu(c)$ with another one in $S \setminus \mu(c)$ cannot make $c$ better off. Hence, $\mu$ cannot be blocked by a worker–firm pair. Moreover, $\mu$ is individually rational since each agent is matched with acceptable agents and whenever a college blocks a subset of assignees it ends up with negative balance with a worse incoming set of students.

**Appendix C  Tuition-Exchange Programs**

We first explain why tuition-exchange programs exist in the first place because some other colleges choose to subsidize faculty directly instead of participating in tuition-exchange programs. Although this may create flexibility for the students, any direct compensation
over $5,250 is taxable income, whereas a tuition-exchange scholarship is not. Tuition exchange is not considered to be an income transfer. Moreover, colleges may not want to switch to such direct-compensation programs from a cost-saving perspective, regardless of the tax benefit to the faculty member. We present a simple back-of-the-envelope calculation to demonstrate these cost savings. There are more than 1800 4-year colleges in the US and at most half of them have membership to at least one tuition exchange program. Suppose \( n \) students are given tuition exchange/remission scholarships a year. Instead, if a college finances the tuition of a faculty member’s child through direct cash compensation, then all tuition exchange colleges will have to pay \( $nT \), where \( T \) is the average full tuition cost of colleges. However, assuming that average qualities and sizes of colleges with and without tuition scholarship are the same, only half of these students will attend a tuition exchange college in return; so the colleges will only get back \( \frac{1}{2}nT \). The remaining \( \frac{1}{2} \) slots will be filled with regular students. Regular students on average pay about half of the tuition thanks to other financial aid programs. For example, 2012 Tuition Discounting Study of the National Association of College and University Business Officers report that incoming freshmen pay on average 56% of full tuition at a private university. Thus, they will only pay \( \frac{1}{4}nT \) to tuition exchange colleges. As tuition exchange scholarships constitute a very small portion of college admissions, this calculation assumes that average tuition payment would not change by establishment of direct cash compensation instead of tuition exchange. Thus, as a result, the colleges will lose in total about \( \frac{1}{4}nT \), which corresponds to one fourth of average full tuition per student. Thus, the total per-student-savings for the faculty member and the college is more than half of tuition payment - assuming one third of the direct compensation is paid in income tax at the margin by the parent.

**The Tuition Exchange Inc (TTEI):** In addition to information provided in the Section 2, here we give more detail. TTEI is a reciprocal scholarship program for children (and other family members) of faculty and staff employed at more than 600 colleges. Member colleges are spread over 47 states and the District of Columbia. Both research universities and liberal arts colleges are members. *US News and World Report* lists 38 member colleges in the best 200 research universities and 46 member colleges in the best 100 liberal arts colleges.

In TTEI, every participating institution determines the number of outgoing students it can certify, as well as how many TTEI awards it will grant to incoming students each year. Then each faculty member submits the TTEI application to the registration office

---

of their college. If the number of applicants is greater than the number of students that
the college is willing to certify, then the college decides whom to certify based on years
of service or some other criterion (internal priority order).

Each student who is certified eligible submits a list of colleges to the liaison office of her
home institution. Each liaison office sends a copy of the TTEI “Certificate of Eligibility” to
the TTEI liaison officer at the participating colleges and universities listed by the eligible
dependents. Certification only means that the student is eligible for a TTEI award; it
is not a guarantee of an award. The eligible student must apply for admission to the
college(s) in which she is interested, following each institution’s application procedures
and deadlines. After admission decisions have been made, the admissions offices or TTEI
liaisons at her listed institutions inform her whether she will be offered a TTEI award.
TTEI scholarships are competitive, and some eligible applicants may not receive them.
That is, the sponsoring institution cannot guarantee that an “export” candidate, regardless
of qualifications, will receive a TTEI scholarship. Institutions choose their scholarship
recipients (“imports”) based on the applicants’ academic profiles.

To collect anecdotal evidence on how much faculty members value the tuition-exchange
benefit, we also conducted an IRB-approved e-mail–delivered online survey in 21 tuition-
exchange colleges (all TTEI members and possibly members of other tuition exchange
programs) using Qualtrics e-mail survey software. Our respondent pool is composed of
150 faculty members (with a 7.5% to 15% response rate). In this pool, there are 48,
56, and 46 assistant, associate, and full professors, respectively. 17% of the respondents
have no child. In order to understand whether tuition-exchange benefits attract faculty
members, we ask how important of a role their college’s membership in a tuition-exchange
program played their acceptance of their offer. According to 19%/60% of the respondents,
the tuition-exchange benefit was extremely important/important in their acceptance de-
cision, respectively. Moreover, according to 23%/73% of the respondents with children,
the tuition-exchange benefit played an extremely important/important role in their ac-
ceptance decision, respectively. In order to understand the value of the tuition-exchange
benefit for faculty, we asked how much annual income they would give up in order to keep
their tuition-exchange benefit. When we consider all respondents, the average annual
value of the tuition-exchange benefit is $7,314 each year in today’s dollars per faculty
member (for the ones with one or more child currently, it is only slightly higher, $8,243).

The Council of Independent Colleges Tuition Exchange Program (CIC-TEP):
CIC-TEP is composed of almost 500 colleges. Most of the member colleges are from
the Midwest or on the East Coast. All full–time employees of the member colleges and
their dependents can benefit from this program. Each college certifies its own employees
eligible based on its own rules. Each member college is required to accept at least three exchange students per year. There is no limitation on the number of exported students. Each certified student also applies for admission directly to the member colleges of her choice. Certified students must be admitted by the host college in order to be considered for the tuition exchange scholarship. Each year more than 1500 students benefit from this program.

**Catholic College Cooperative Tuition Exchange (CCCTE):** CCCTE is composed of 70 member colleges. Each member college certifies its employees as eligible based on its own rules. Dependents must be admitted by the host college before applying for the tuition exchange scholarship. Admission to the host college does not guarantee the scholarship. Each member college can have at most five more import students than its exports. There is no limitation on the number of students it exports in a given academic year.

**Great Lakes Colleges’ Association (GLCA):** GLCA is composed of thirteen liberal arts colleges in Pennsylvania, Michigan, Ohio, and Indiana. Each member college determines the eligibility of its employees based on its own rules. All other policies are determined by the host colleges. Each accepted student pays a fee equal to 15% of the GLCA mean tuition. The remaining tuition is paid by the home college.

**Associated Colleges of the Midwest (ACM):** ACM is composed of fourteen liberal arts colleges in Wisconsin, Minnesota, Iowa, Illinois, and Colorado. Eligibility is determined based on the home college rules. If a certified student is eligible for the host college’s tuition remission program, then she is considered eligible for the tuition exchange scholarship. Each host college compensates 50% tuition to all imported students. The remaining portion of the tuition is paid by the home college and the student. The share of the student cannot be more than 20% of tuition.

**Faculty and Staff Children Exchange Program (FACHEX):** FACHEX is composed of 28 Jesuit colleges. Each student first applies to be admitted by the host college. Admission to the host college does not guarantee receiving tuition exchange scholarship. For each college, the number of import cannot exceed the number of its export by three.

**Council for Christian Colleges and Universities Tuition-Waiver Exchange Program (CCCU-TWEP):** CCCU-TWEP is composed of 100 colleges. Each member college must accept at least one exchange student. In order to receive tuition exchange scholarship, each student needs to be admitted by the host college.
Appendix D   Temporary Worker-Exchange Programs

D.1   Teacher Exchange

The Fulbright Teacher Exchange Program, established by an act of the US Congress in 1946, provides opportunities to school teachers in US to participate in a direct exchange of positions with teachers from countries, including the Greece, Finland, Netherlands, India, Mexico, and the United Kingdom. Matching procedure is arranged by the Fulbright program staff, and each candidate and each school must be approved before the matchings are finalized.

The Commonwealth Teacher Exchange Programme (CTEP) was founded by the League for the Exchange of Commonwealth Teachers more than 100 years ago. Participant teachers exchange their jobs and homes with each other usually for a year, and they stay employed by their own school. Countries participating to this program are Australia, Canada, and the UK. More than 40,000 teachers have benefited from the CTEP. Principals have the right to veto any proposed exchange they think will not be appropriate for their school.

The Educator Exchange Program is organized by the Canadian Education Exchange Foundation. The program includes reciprocal interprovincial and international exchanges. Destinations for international teacher exchanges are Australia, Denmark, France, Germany, Switzerland, the UK, and Colorado, US. Matches are determined based on the preferences, family needs, accommodations offered, and accommodations needed.

The Manitoba Teacher Exchange enables teachers in Manitoba to exchange their positions with teachers in Australia, the UK, the US, Germany, and other Canadian provinces. Once a potential match is found, the incoming teacher’s information is sent to the Manitoba applicant, the principal of the school, and the employing authority. Acceptance of all these agents is required for the completion of the exchange.

In the Saskatchewan Teacher Exchange, public school teachers with at least five years of experience can apply for exchange positions with teachers in the UK, the US, and Germany. Potential exchange candidates are determined based on similar teaching assignments and personal and professional interests and they are sent to applicant’s director of education. If the potential exchange candidates are considered acceptable by the the applicant’s director and principals, then the applicant will consider the candidate. The exchange is finalized once the applicant accepts it.

The Northern Territory Teacher Exchange Program is a reciprocal program in which teachers in Northern Territory exchange positions with teachers from the UK, Canada, the US, New Zealand, and the Australian States of New South Wales, Queens-
land, South Australia, and Western Australia. When a potential match is found for an applicant, the applicant and her school principal decide whether to accept or reject the proposal. The match is finalized when both sides accept it.

**The Western Australian Teacher Exchange** is a reciprocal program. The exchanges can be done with teachers from school systems in different states, territories, or countries. The match is finalized after the approval of the principals of both sides.

**The Rural Teacher Exchange (TRTE)** is a reciprocal program which gives opportunity to teachers in more than 800 rural and remote schools in New South Wales to exchange their positions. Exchanges are selected via centralized mechanism which considers submitted preference list. However, if a teacher can find a possible exchange counterpart, then they can exchange their positions before entering the central mechanism.

### D.2 Clinical Exchange

In the **International Clinical Exchange Program**, medical students exchange positions with other medical students from other countries. The program is run by the International Federation of Medical Students’ Association. Every year, approximately 13,000 students exchange their positions. The exchanges are done bilaterally: for every student who goes to a certain country, one student from that country can come to the student’s home country. In a county, the exact number of available positions available for another country is determined by the number of contracts signed between both countries.

**The MICEFA Medical Program** has enabled medical students in France and US to exchange their positions for one to two months for 30 years. Students are exchanged on a one-to-one basis and each exchange students pays tuition to her home institute. Faculty members can also benefit from this exchange program. Each faculty member receives salary from the host institute.

### D.3 Student Exchange

**The National Student Exchange (NSE)**, established in 1968, is composed of nearly 200 colleges from the United States, Canada, Guam, Puerto Rico, and the US Virgin Islands. More than 105,000 undergraduate students have exchanged their colleges through NSE. Exchange students pay either the in-state tuition of their host institution or the normal tuition of their home campus.

**The University of California Reciprocal Exchange program (UCREP)** enables the students of the University of California system to study in more than 120 universities from 33 countries. Around 4,000 students benefit from this program annually. Exchange
students are selected by the home university. This is a reciprocal exchange program and it aims to balance the costs and benefits of import and export students for each university.  

The University Mobility in Asia and the Pacific Exchange Program (UMAEP), established in 1993, is a student exchange program between 500 universities in 34 Asia-Pacific countries. UMAEP involves two programs: a bilateral exchange program and a multilateral exchange program. In the bilateral exchange program, home colleges select the exchange students and exchanges are done through bilateral agreements signed between the member colleges. In the multilateral exchange program, host universities select the incoming exchange students. 

The International Student Exchange (ISE), founded in 1979, is a reciprocal program. Around 40,000 students from 45 countries have benefited from ISE. Each exchange student pays tuition to her home college. Reciprocity is based on the number of incoming and outgoing students. 

The Erasmus Student Exchange Program is a leading exchange program between the universities in Europe. Close to 3 million students have participated since it started in 1987. The number of students benefiting from the program is increasing each year; in 2011, more than 231,408 students attended a college in another member country as an exchange student. The number of member colleges is more than 4,000. Each college needs to sign bilateral agreements with the other member institutions. In particular, the student exchanges are done between the member universities that have signed a bilateral contract with each other. The bilateral agreement includes information about the number of students who will be exchanged between the two universities in a given period. The selection process of the exchange students is mostly done as follows. The maximum number of students that can be exported to a partner university is determined based on the bilateral agreement with that partner and the number of students who have been exported since the agreement was signed. The students submit their list of preferences over the partner universities to their home university. Each university ranks its own students based on predetermined criteria, e.g., GPA and seniority. Based on the ranking, a serial dictatorship mechanism is applied to place students in the available slots. Finally, the list of students who received slots at the partner universities is sent to the partners. The partner universities typically accept all the students on the list. An exchange student pays her tuition to her own college, not the one importing her.  

There are huge imbalances between the number of students exported and imported by each country. Moreover, countries with high positive balances are not often willing to match the quota requests of the net-exporter countries. This precautionary behavior may lead to inefficiencies as in tuition-exchange markets.
D.4 Scientific Exchange

The Mevlana Exchange Program aims to exchange academic staff between Turkish universities and universities in other countries. Turkish public universities are governed by the Turkish Higher Education Council and professors are public servants. Therefore, the part of the exchange that is among public universities can be seen as a staff-exchange program, while the exchange among public and private Turkish universities and foreign universities can be seen as a worker-exchange program. Any country can join this program. In 2013, around 1,000 faculty members benefited from this program.

Appendix E Proofs of Appendix A

Proof of Proposition 3. We prove existence by showing that for any tuition-exchange market there exists an associated college admission market and the set of stable matchings are the same under both markets. Under Assumption 3, we fix a tuition exchange market \([q, c, \succsim]\). We first introduce an associated college admissions market, i.e., a Gale-Shapley (1962) two-sided many-to-one matching market, \([S, C, q, P_S, \overline{P}_C]\), where the set of students is \(S\); the set of colleges is \(C\); the quota vector of colleges for admissions is \(q\); the preference profile of students over colleges is \(P_s\), which are all the same entities imported from the tuition exchange market; and the preference profile of colleges over the set of students is \(\overline{P}_C\), which we construct as follows: for all \(T \subset E\) (i.e., the set of eligible students) such that \(|T| < q_c\) and \(i, j \in E \setminus T\), (i) \(i P_c j \implies (T \cup i) \overline{P}_c (T \cup j)\), (ii) \(i P_c \emptyset \implies (T \cup i) \overline{P}_c T\), and (iii) \(T \overline{P}_c (T \cup k)\) for all \(k \in S \setminus E\). We fix \(C\) and \(S\) and represent such a college admission market as \([q, P_S, \overline{P}_C]\). In this college admissions market, a matching \(\overline{m}\) is a correspondence \(\overline{m} : C \cup S \rightarrow C \cup S \cup \emptyset\) such that (1) \(\overline{m}(c) \subseteq S\) where \(|\overline{m}(c)| \leq q_c\) for all \(c \in C\); (2) \(\overline{m}(s) \in \{C \cup \emptyset\}\) where \(|\overline{m}(s)| = 1\) for all \(s \in S\), and (3) \(s \in \overline{m}(c) \iff \overline{m}(s) = c\) for all \(c \in C\) and \(s \in S\). A matching \(\overline{m}\) is *individually rational* if \(\overline{m}(s) R_s c_0\) for all \(s \in S\), and, for all \(i \in \overline{m}(c)\), we have \(i \overline{P}_c \emptyset\) for all \(c \in C\). A matching \(\mu\) is *nonwasteful* if there does not exist any \((c, s) \in C \times S\) such that (1) \(c P_s \overline{m}(s)\), (2) \(|\overline{m}(c)| < q_c\), and (3) \(s \overline{P}_c \emptyset\). A matching \(\overline{m}\) is *blocked by a pair* \((c, s) \in C \times S\) if \(c P_s \mu(s)\), and there exists \(s' \in \overline{m}(c)\) such that \(s \overline{P}_c s'\). A matching \(\overline{m}\) is *stable* in a college admission market if it is individually rational, nonwasteful, and not blocked by any pair.

By our construction \(\overline{P}_C\) is responsive; hence there exists at least one stable matching in \([q, P_S, \overline{P}_C]\) (cf. Gale and Shapley, 1962; Roth, 1985). Let \(\overline{m}\) be a stable matching in \([q, P_S, \overline{P}_C]\). We first show that \(\overline{m}\) is also a matching in \([q, c, \succsim]\). By the definition of a matching in a college admission market, the first three bullets of the definition of a matching in a tuition exchange market hold. Due to individual rationality, \(\mu(s) = c_0\) for
all $s \notin E$. Hence, $\pi$ is a matching in $[q, e, \succeq]$.

Now, we show that $\pi$ is stable in $[q, e, \succeq]$. Due to individually rationality of $\pi$ in the college admission market, $\mu(s) R_c e_0$ and $s P_i \emptyset$ for all $s \in \pi(c)$ and $c \in C$. By Assumption 3 and the definition of individual rationality in the tuition-exchange market, $\pi$ is individually rational in $[q, e, \succeq]$. Whenever there exists $s \in S$ such that $c P_s \pi(s)$, then either $s \in S \setminus E$ or $\pi \succ_c \mu'$ for all $\mu' \in M$, where $s \in \mu'(c) \subset \pi(c) \cup s$ and $\pi(s') = \mu'(s')$ for all $s' \in S \setminus (\pi(c) \cup s')$. This follows from the definition of stability and construction of the college preferences in the associated college admission market and Assumption 3. Hence, $\pi$ is stable in $[q, e, \succeq]$.

Finally, we show that if a matching is not stable in $[q, P_s, \overline{P}_C]$, then it is either not a matching or unstable in $[q, e, \succeq]$. Note that any matching in $[q, e, \succeq]$ is also a well-defined matching in $[q, P_s, \overline{P}_C]$. Hence, it suffices to show that any matching $\mu$ in $[q, e, \succeq]$ that is not stable in $[q, P_s, \overline{P}_C]$ fails to be stable in $[q, e, \succeq]$. If $\mu$ is blocked by an agent in $[q, P_s, \overline{P}_C]$, then by our assumption on the preferences it is also blocked by the same agent in $[q, e, \succeq]$. If $\mu$ is wasteful in $[q, P_s, \overline{P}_C]$, then there exists a college-student pair $(c, s)$ such that her addition to the set of students admitted by $c$ in $\mu$ is both preferred by $c$ and herself in $[q, e, \succeq]$. Similarly, if $(c, s)$ is a blocking pair in $[q, P_s, \overline{P}_C]$ then by our preference construction and stability definition $(c, s)$ is a blocking pair in $[q, e, \succeq]$. Thus, if $\mu$ is a stable matching in $[q, e, \succeq]$, it is also stable in $[q, P_s, \overline{P}_C]$.

Hence, the set of stable matchings under $[q, e, \succeq]$ and the set of stable matchings in $[q, P_s, \overline{P}_C]$ are the same.  

**Proof of Proposition 5.** Under Assumption 3, we fix a market $[q, e, \succeq]$. The case in which we have a unique stable matching in $[q, e, \succeq]$ is trivial. Hence, we consider the case in which there are at least two stable matchings. Let $\nu$ and $\mu$ be any two stable matchings of $[q, e, \succeq]$. By the proof of Proposition 3, $\nu$ and $\mu$ are also stable under the associated college admission market $[q, P_s, \overline{P}_C]$. Let $S^\nu$ and $S^\mu$ be the set of students assigned to a college in $\nu$ and $\mu$, respectively. Due to Assumption 3 Part 3 and individual rationality, $M^\mu_c = \mu(c)$, $M^\nu_c = \nu(c)$ for all $c \in C$. In the rural hospital theorem (Roth, 1986) it is shown that the number of students assigned to a college is the same in all stable matchings, $|\nu(c)| = |\mu(c)|$ for each $c \in C$. Moreover, the set of students assigned to a real college is the same in all stable matchings, i.e., $S^\nu = S^\mu$. Since $X^\mu_c = S^\mu \cap S_c$, $X^\nu_c = S^\nu \cap S_c$, and $S^\nu = S^\mu$, we have $X^\mu_c = X^\nu_c$. Then, $b^\mu_c = |\mu(c)| - |S^\mu \cap S_c| = |\nu(c)| - |S^\nu \cap S_c| = b^\nu_c$ for all $c \in C$.  

We first state and prove the following Lemma, which is used in proving Proposition 6 and Theorem 11:

**Lemma 2** Under Assumption 3, let $\hat{\pi}$ be a stable matching of $[q, e, \succeq]$ and $\tilde{\pi}$ be a stable
matching of \([(q_c, q_{c-1}), (\tilde{e}_c, \tilde{e}_{c-1}), \tilde{z}]\) where \(\tilde{e}_c = e_c + 1\), and \(\tilde{q}_c = \tilde{q}_c\) if \(|\tilde{\pi}(c)| = \tilde{q}_c\) and \(\tilde{q}_c \geq \tilde{q}_c\) otherwise. Then we have \(b^*_{q_c} \in \{b^{*}_{q_c} - 1, b^{*}_{q_c}\}\) and \(b^*_{c'} \in \{b^{*}_{c'} - 1, b^{*}_{c'} + 1\}\) for all \(c' \in C \setminus c\).

**Proof.** Denote the newly certified student of \(c\) by \(i\) in \([(q_c, q_{c-1}), (\tilde{e}_c, \tilde{e}_{c-1}), \tilde{z}]\). The number of positions filled by each college is the same at every stable matching by Proposition 5. Moreover, \(\tilde{\pi}\) is stable in the associated college admissions market \([\tilde{q}, P_S, \overrightarrow{P}_{C}]\) by the proof of Proposition 3. Thus, without loss of generality, we assume \(\tilde{\pi}\) to be the outcome of the (student-proposing) DA algorithm in \([\tilde{q}, P_S, \overrightarrow{P}_{C}]\).

First, consider the market \([(q_c, q_{c-1}), (\tilde{e}_c, \tilde{e}_{c-1}), \tilde{z}]\). Let \([(q_c, q_{c-1}), P_S, \overrightarrow{P}_{C}]\) be the associated college admissions market. If \(|\tilde{\pi}(c)| < \tilde{q}_c\), then adding new seats to an underdemanded college will not change the set of students assigned to \(c\), and the DA selects the same outcome in \([\tilde{q}, P_S, \overrightarrow{P}_{C}]\) and \([(q_c, q_{c-1}), P_S, \overrightarrow{P}_{C}]\). If \(|\tilde{\pi}(c)| = \tilde{q}_c\), \(\tilde{q}_c = \tilde{q}_c\) by assumption. Hence, the DA selects the same outcome in \([(q_c, q_{c-1}), P_S, \overrightarrow{P}_{C}]\) and \([\tilde{q}, P_S, \overrightarrow{P}_{C}]\).

Denote the associated college admissions market of \([(q_c, q_{c-1}), (\tilde{e}_c, \tilde{e}_{c-1}), \tilde{z}]\) by \([(\tilde{q}, \tilde{q}_{c-1}), P_S, \overrightarrow{P}_{C}]\). We will apply the sequential DA algorithm introduced by McVitie and Wilson (1971) in \([(\tilde{q}, \tilde{q}_{c-1}), P_S, \overrightarrow{P}_{C}]\), where the newly certified agent \(i\) will be considered at the end. Let \(\tilde{\pi}\) be the outcome of the DA for \([(\tilde{q}, \tilde{q}_{c-1}), P_S, \overrightarrow{P}_{C}]\).

Let \(C_\prec\) be the set of colleges that could not fill all their seats, and \(C_\succ\) be the set of colleges that did, in \(\tilde{\pi}\). Formally, \(C_\prec = \{c \in C : |\tilde{\pi}(c)| < \tilde{q}_c\}\) and \(C_\succ = \{c \in C : |\tilde{\pi}(c)| = \tilde{q}_c\}\). Now, when it is the turn of \(i\) to apply in the sequential version of the student-proposing DA, the current tentative matching is \(\tilde{\pi}\). After \(i\) starts making applications in the algorithm, let \(\tilde{c}\) be the first college that does not reject \(i\). Since \(\emptyset \| P_c i\), \(c \neq \tilde{c}\).

In the rest of the proof, as we run the sequential DA, we run the following cases iteratively, starting with student \(i\):

1. If \(\tilde{c} = q_0\), then the algorithm terminates; \(b^* = b^*\).
2. If \(\tilde{c} \in C_\prec\), then \(i\) will be assigned to \(\tilde{c}\) and the algorithm terminates; \(b^*_{c'} = b^*_{c'} - 1\), \(b^*_{c'} = b^*_{c'} + 1\), and \(b^*_{c'} = b^*_{c'}\) for all \(c' \in C \setminus \{c, \tilde{c}\}\).
3. If \(\tilde{c} \in C_\succ\), then student \(\tilde{i}\) who has the lowest priority among the students in \(\tilde{\pi}(\tilde{c})\) is rejected in favor of \(i\). We consider two cases:
   3.a. Case \(\tilde{i} \in S_\succ\): The net balance of no college will change from the beginning, and we continue from the beginning above, again using student \(\tilde{i}\) instead of \(i\).
   3.b. Case \(\tilde{i} \notin S_\succ\): The instantaneous balance of \(c\) will deteriorate by 1 as \(i\) is tentatively accepted. Now, it is \(\tilde{i}\)'s turn in the sequential DA to make offers. In this series of offers, suppose the first college that does not reject student \(\tilde{i}\) is \(\tilde{c}\). Denote the home college of \(\tilde{i}\) by \(c'\) (note that \(c' \neq c\)).
3.b.i. If $\tilde{c} \in c_0 \cup (C_\prec)$, then the algorithm will terminate, and $b^\pi_c \in \{b^\pi_c - 1, b^\pi_c\}, b^\pi_c \in \{b^\pi_c, b^\pi_c + 1\}$ for all $\tilde{c} \in C \setminus c$.

3.b.ii. If $\tilde{c} \in C_\prec$, then the lowest-priority student held by $\tilde{c}$ will be rejected in favor of $i$. Let this student be $\tilde{i}$. There are two further cases:

3.b.ii.A. Case $\tilde{i} \in S_c$: Then, $\tilde{c} \neq c$. The instantaneous balance of $c$ will increase by 1, and we will start from the beginning again with $\tilde{i}$ instead of $i$. The total change in $c$'s balance since the beginning will be 0. Also, no other college's balance has changed since the beginning.

3.b.ii.B. Case $\tilde{i} \notin S_c$: We start from Step 3b above with student $\tilde{i}$ instead of $i$.

Thus, whenever we continue from the beginning, the instantaneous balance of $c$ is $b^\pi_c$, and whenever we continue from Step 3b, the instantaneous balance of $c$ is $b^\pi_c - 1$ or $b^\pi_c$ and the instantaneous balances of all other colleges either increase by one or stay the same. Due to finiteness, the algorithm will terminate at some point at Steps 1 or 2, or Steps 3b.i or 3b.ii; and the net balance of $c$ at the new DA outcome will be $b^\pi_c$ or $b^\pi_c - 1$. Moreover, whenever the algorithm terminates, the net balance of any other college has gone up by one or stayed the same.

We are ready to prove the results stated in the Appendix A:

**Proof of Proposition 6.** Let $[\bar{q}, P_S, \overline{P_C}]$ and $[(\bar{q}, \bar{c}, \bar{z}_c), (\bar{q}, \bar{c}, \bar{z}_c), (\bar{e}_c + 1, \bar{z}_c), (\bar{e}_c, \bar{z}_c)]$, respectively. Let $\hat{\pi}$ and $\bar{\pi}$ be the outcome of the DA in $[\bar{q}, P_S, \overline{P_C}]$ and $[(\bar{q}, \bar{c}, \bar{z}_c), (\bar{q}, \bar{c}, \bar{z}_c), (\bar{e}_c + 1, \bar{z}_c), (\bar{e}_c, \bar{z}_c)]$, respectively. By Propositions 3 and 5, it is sufficient to prove the proposition for $\hat{\pi}$ and $\bar{\pi}$. Note that $M^\pi_c = \hat{\pi}(c)$ by Assumption 3 Part 3, and $\hat{\pi}$ is stable.

Two cases are possible:

Case 1: $b^\pi_c < 0$: We have $|\hat{\pi}(c)| = |M^\pi_c| < |X^\pi_c| \leq \hat{e}_c \leq \bar{q}_c$. Then, by Lemma 2, $b^\pi_c \in \{b^\pi_c - 1, b^\pi_c\}$.

Case 2: $b^\pi_c \geq 0$: We have two cases again:

2.a. $|\hat{\pi}(c)| < \bar{q}_c$ or $\bar{q}_c = \bar{q}_c$: By Lemma 2, $b^\pi_c \in \{b^\pi_c - 1, b^\pi_c\}$.

2.b. $|\hat{\pi}(c)| = \bar{q}_c$ and $\bar{q}_c = \bar{q}_c + k$ for $k > 0$: Denote the newly certified student of $c$ by $i$ in market $[(\bar{q}_c, \bar{q}_c), (\bar{e}_c, \bar{e}_c), (\bar{z}_c)]$. We first consider the outcome of the DA in the associated college admissions market of $[(\bar{q}_c, \bar{q}_c), (\bar{e}_c, \bar{e}_c), (\bar{z}_c)]$, which we denote by $\pi''$. We first show that the number of students imported by $c$ in $\pi''$ cannot be less than the one in $\hat{\pi}$. Let $C_\prec = \{\tilde{c} \in C \setminus \hat{c} : |\hat{\pi}(c)| < \bar{q}_c\}$. By our construction, in any stable matching of the associated college admissions market all students in $S \setminus E$ are assigned to $c_\emptyset$. Due to the nonwastefulness of $\hat{\pi}$, $\hat{\pi}(s)P_\delta \hat{c}$ for all $s \in E \setminus \hat{\pi}(\hat{c})$ and $\hat{c} \in C_\prec$. We know that the DA is resource monotonic: when the number of seats (weakly) increases at each college, then every student will be weakly better off (cf. Kesten, 2006). That is, $\pi''(s)R_\delta \hat{\pi}(s)$ for all
Thus, by Lemma 2, as we increase the eligibility quota of college admission quota at \( \tilde{b} \), we can say that if a student is assigned to a college in \( \tilde{\pi} \), then she will also be assigned to a college in \( \pi'' \). Hence, we can write:

\[
\sum_{c' \in C} |\pi''(c')| \geq \sum_{c' \in C} |\tilde{\pi}(c')|.
\]

(1)

Note that the difference between the left-hand side and the right-hand side of the equation can be at most \( k \). This follows from the fact that in \( \pi'' \) no new student will be assigned to a college in \( C_\prec \), the number of students assigned to other colleges can increase only for \( c \), and the maximum increment is \( k \).

By combining nonwastefulness and resource monotonicity we can write:

\[
\sum_{\tilde{c} \in \hat{\pi}} |\pi''(\tilde{c})| \leq \sum_{\tilde{c} \in \hat{\pi}} |\tilde{\pi}(\tilde{c})|.
\]

(2)

Then, if we subtract the left-hand side of Equation 2 from the left-hand side of Equation 1 and the right-hand side of Equation 2 from the right-hand side of Equation 1, we get the following inequality:

\[
\sum_{c' \in C \setminus C_\prec} |\pi''(c')| \geq \sum_{c' \in C \setminus C_\prec} |\tilde{\pi}(c')|.
\]

(3)

Given that each college in \( C \setminus C_\prec \) fills its seats in \( \tilde{\pi} \), when we subtract \( \sum_{c' \in C \setminus (C_\prec \cup c)} \widetilde{q}_{c'} \) from both sides of Equation 3, we get the following inequality:

\[
|\pi''(c)| + \sum_{c' \in C \setminus (C_\prec \cup c)} (|\pi''(c')| - \widetilde{q}_{c'}) \geq |\tilde{\pi}(c)|.
\]

(4)

The term \( \sum_{c' \in C \setminus (C_\prec \cup c)} (|\pi''(c')| - \widetilde{q}_{c'}) \) is nonnegative since \( |\pi''(c')| \leq \widetilde{q}_{c'} \) for all \( c' \in C \setminus (C_\prec \cup c) \). Therefore, \( |\pi''(c)| \geq |\tilde{\pi}(c)| \).

If \( |\pi''(c)| = |\tilde{\pi}(c)| \) then \( |\pi''(c')| = |\tilde{\pi}(c')| \) for all \( c' \in C \). This follows from Equation 4, Equation 2, and the fact that \( |\pi''(c')| \leq |\tilde{\pi}(c')| \) for all \( c' \in C \setminus \{c\} \). Therefore, \( c \) cannot export and import more students, and \( \tilde{b}_{c}^{\pi''} = \tilde{b}_{c}^{\tilde{\pi}} \). If \( |\pi''(c)| > |\tilde{\pi}(c)| \), then at most \( k \) more students can be assigned to a college in \( \pi'' \) among the eligible students who were not assigned to a college in \( \tilde{\pi} \). It is possible that some of the students belong to \( S_c \). Thus, \( \tilde{b}_{c}^{\pi''} \in \{\tilde{b}_{c}^{\pi''} - 1, \tilde{b}_{c}^{\pi''}\} \), and hence, \( \tilde{b}_{c}^{\pi} \in \{\tilde{b}_{c}^{\pi} - 1, \tilde{b}_{c}^{\pi}, ..., \tilde{b}_{c}^{\pi} + k\} \).

Thus, by Lemma 2, as we increase the eligibility quota of college \( c \) by 1 and keep the admission quota at \( \tilde{q}_c \), we have \( \tilde{b}_{c}^{\pi''} \in \{\tilde{b}_{c}^{\pi''} - 1, \tilde{b}_{c}^{\pi''}\} \), and hence, \( \tilde{b}_{c}^{\pi} \in \{\tilde{b}_{c}^{\pi} - 1, \tilde{b}_{c}^{\pi}, ..., \tilde{b}_{c}^{\pi} + k\} \).

49
Proof of Theorem 10. Given Proposition 6, when \( c \) decreases its certification quota by one and keeps its admission quota the same, its balance in any stable outcome of the new market will either be the same or increase by one. Since \( c \) will have a nonnegative balance in any stable outcome of the market \([\hat{q}, (\hat{e}_c = 0, \hat{e}_{c-1}), \leq]\), there exists \( 0 \leq \hat{e}_c \leq \hat{e}_c \) such that \( c \) has a zero–balance in every stable matching of the market \([\hat{q}, (\hat{e}_c, \hat{e}_{c-1}), \leq]\).

Proof of Theorem 11. We consider two problems: \([\hat{q}, \hat{e}, \leq]\) and \([(q_c', \hat{q}_{c-1}), (\hat{e}_c - 1, \hat{e}_{c-1}), \leq]\) with \( \hat{q}_c \geq \hat{e}_c \) and \( \hat{q}_c \geq q_c' \geq \hat{e}_c - 1 \) such that for \( c \), \( b_{\mu}^c < 0 \) for a stable matching \( \mu \) of the first market. Let \( \mu' \) be an arbitrary stable matching of the second market. We want to show that \( b_{\mu}^c \geq b_{\mu'}^c \). From Proposition 6, we know that \( b_{\mu'}^c < 0 \) or \( b_{\mu'}^c = 0 \). By Proposition 5, without loss of generality we assume that \( \mu \) and \( \mu' \) are the outcome of the sequential DA algorithm for the associated college admissions market of \([\hat{q}, \hat{e}, \leq]\) and \([(q_c', \hat{q}_{c-1}), (\hat{e}_c - 1, \hat{e}_{c-1}), \leq]\), respectively. We have two cases:

**Case 1:** \( b_{\mu'}^c < 0 \). We have \( |\mu'(c)| = |M_\mu'| < |X_\mu'| \leq e_c - 1 \leq \min\{\hat{q}_c, q_c'\} \). Hence, as \( c \) did not fill its admission quota at \( \mu' \) under both \( \hat{q}_c \) and \( q_c' \), in market \([\hat{q}, (\hat{e}_c - 1, \hat{e}_{c-1}), \leq]\) \( \mu' \) will still be the outcome of DA for the associated college admissions market. When we add a new student \( i \) from \( c \) to the set of eligible students, we obtain \([\hat{q}, \hat{e}, \leq]\). By Lemma 2, we have \( b_{\mu'}^{c'} = \{b_{\mu'}^c, b_{\mu'}^c + 1\} \) for all \( c' \in C \setminus c \).

**Case 2:** \( b_{\mu'}^c = 0 \). There are two possibilities: (a) \( |\mu'(c)| < q_c' \) and (b) \( |\mu'(c)| = q_c' \).

2.a. If \( |\mu'(c)| < q_c' \), then by Lemma 2, we have \( b_{\mu'}^{c'} = \{b_{\mu'}^c, b_{\mu'}^c + 1\} \) for all \( c' \in C \setminus c \).

2.b. If \( |\mu'(c)| = q_c' \), then \( |\mu'(c)| = \hat{e}_c - 1 = q_c' \). We first increase the admission quota of \( c \) from \( q_c' \) to \( \hat{q}_c \) and keep its eligibility quota at \( \hat{e}_c - 1 \). Suppose the number of students assigned to \( c \) decreases at the outcome of the DA under the associated college admissions market of \([\hat{q}, (\hat{e}_c - 1, \hat{e}_{c-1}), \leq]\), which we denote by \( \mu'' \), i.e., \( |\mu''(c)| > |\mu'(c)| = \hat{e}_c - 1 \). Thus, \( b_{\mu''}^c > 0 \). When we also increase the eligibility quota of \( c \) from \( \hat{e}_c - 1 \) to \( \hat{e}_c \), then by Lemma 2, \( b_{\mu''}^c \in \{b_{\mu''}^c - 1, b_{\mu''}^c \} \), and hence, \( b_{\mu''}^c \geq 0 \). However, this contradicts the fact that \( b_{\mu}^c < 0 \). Therefore, \( |\mu''(c)| = |\mu'(c)| = q_c' \leq \hat{q}_c \). Hence, under both associated college admissions problems of \([(q_c', \hat{q}_{c-1}), (\hat{e}_c - 1, \hat{e}_{c-1}), \leq]\) and \([\hat{q}, (\hat{e}_c - 1, \hat{e}_{c-1}), \leq]\), the DA chooses the same matching, i.e., \( \mu'' = \mu' \). When we increase the eligibility quota of \( c \) from \( \hat{e}_c - 1 \) to \( \hat{e}_c \) and keep the admission quota at \( \hat{q}_c \), the DA outcome changes from \( \mu'' = \mu' \) to \( \mu \) under the associated college admissions market. By Lemma 2, we have \( b_{\mu'}^{c'} \in \{b_{\mu'}^{c'}, b_{\mu'}^{c'} + 1\} \) for all \( c' \in C \setminus c \).

In either case, \( b_{\mu}^c \leq b_{\mu}^c \).
Appendix F  Structure of Stable Matchings

In this Appendix, we inspect the structure of stable matchings, as our stability concept is novel. In the college admissions market, there always exist student–optimal and college–optimal Gale–Shapley–stable matchings (cf. Gale and Shapley, 1962; Roth, 1985).\footnote{A matching is student–(or college–)optimal stable if it is preferred to all the other stable matchings by all students (or colleges).} Under Assumption 3, we can guarantee the existence of college– and student–optimal stable tuition–exchange matchings. This result’s proof also uses the associated Gale–Shapley college admissions market for each tuition–exchange market and the properties of Gale–Shapley stable matchings in these markets.\footnote{The lattice property of Gale–Shapley–stable college–admissions matchings can also be used to prove an analogous lattice property for stable matchings in tuition–exchange markets under Assumption 3. We skip it for brevity.}

**Proposition 7** Under Assumption 3, there exist college– and student–optimal matchings in any tuition-exchange market.

**Proof of Proposition 7.** By the proof of Proposition 3, Gale and Shapley (1962), and Roth (1985), there exists a student-optimal stable matching for each tuition-exchange market. By Assumption 3 Part 1 and Proposition 5, colleges compare only the stable matchings through the admitted set of students. By Gale and Shapley (1962) and Roth (1985), there exists a college-optimal stable matching for each tuition-exchange market.

Appendix G  Further Discussion on 2S-TTC Mechanism

We illustrate the dynamics of the 2S-TTC mechanism with an example below:

**Example 1** Let $C = \{a, b, c, d, e\}$, $S_a = \{1, 2\}$, $S_b = \{3, 4\}$, $S_c = \{5, 6\}$, $S_d = \{7, 8\}$, and $S_e = \{9\}$. Let each college certify all its students as eligible and $q = (2, 2, 2, 1, 1)$. The internal priorities and the rankings of agents associated with their preferences over
matchings are given as:

<table>
<thead>
<tr>
<th></th>
<th>$P_a$</th>
<th>$P_b$</th>
<th>$P_c$</th>
<th>$P_d$</th>
<th>$P_e$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\triangleright_a$</td>
<td>3</td>
<td>5</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>$\triangleright_b$</td>
<td>4</td>
<td>1</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>$\triangleright_c$</td>
<td>5</td>
<td>6</td>
<td>4</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>$\triangleright_d$</td>
<td>9</td>
<td>2</td>
<td>9</td>
<td>9</td>
<td>7</td>
</tr>
<tr>
<td>$\triangleright_e$</td>
<td>7</td>
<td>7</td>
<td>7</td>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>$\varnothing$</td>
<td>$\varnothing$</td>
<td>$\varnothing$</td>
<td>$\varnothing$</td>
<td>$\varnothing$</td>
<td>$\varnothing$</td>
</tr>
</tbody>
</table>

$P_1$  $P_2$  $P_3$  $P_4$  $P_5$  $P_6$  $P_7$  $P_8$  $P_9$
\begin{align*}
\text{b} & \quad \text{b} & \quad \text{a} & \quad \text{c} & \quad \text{b} & \quad \text{a} & \quad \text{c} & \quad \text{c} \\
\text{c} & \quad \text{c} & \quad \text{c} & \quad \text{a} & \quad \text{a} & \quad \text{b} & \quad \text{a} & \quad \text{c} & \quad \text{d} \\
\varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing & \quad \varnothing
\end{align*}

Let $o_e$ and $o_a$ be the vectors representing the eligibility and admission counters of colleges, respectively. Then we set $o_e = (2, 2, 2, 2, 1)$ and $o_a = (2, 2, 2, 1, 1)$.

**Round 1:** The only cycle formed is $(b, 3, a, 1)$. Therefore, 1 is assigned to $b$ and 3 is assigned to $a$. Observe that although college $a$ is the most-preferred college of student 6, she is not acceptable to $a$, and hence, she points to college $b$ instead. The updated counters are $o_e = (1, 1, 2, 2, 1)$ and $o_a = (1, 1, 2, 1, 1)$.

**Round 2:** The only cycle formed in Round 2 is $(c, 6, b, 4)$. Therefore, 6 is assigned to $b$ and 4 is assigned to $c$. The updated counters are $o_e = (1, 0, 1, 2, 1)$ and $o_a = (1, 0, 1, 1, 1)$. College $b$ is removed.

**Round 3:** The only cycle formed in Round 3 is $(a, 2, c, 5)$. Therefore, 5 is assigned to $a$ and 2 is assigned to $c$. The updated counters are $o_e = (0, 0, 2, 1)$ and $o_a = (0, 0, 0, 1, 1)$. 52
Colleges $a$ and $c$ are removed.

**Round 4:** The only cycle formed in Round 4 is $(c, 7)$. Therefore, 7 is assigned to $c$. Given that we have a trivial cycle, we only update $o_c$. The updated counters are $o_c = (0, 0, 0, 1, 1)$ and $o_a = (0, 0, 0, 1, 1)$.

**Round 5:** The only cycle formed at this round is $(e, 9, d, 8)$. Therefore, 8 is assigned to $e$ and 9 is assigned to $d$. The updated counters are $o_c = (0, 0, 0, 0, 0)$ and $o_a = (0, 0, 0, 0, 0)$.

All agents are assigned, so the algorithm terminates and its outcome is given by matching

$$
\mu = \begin{pmatrix}
  a & b & c & d & e \\
  \{3, 5\} & \{1, 6\} & \{2, 4\} & 9 & 8 \\
\end{pmatrix}.
$$

It would be good to point out a few simple observations regarding regular TTC and 2S-TTC. Since students may not be able to point to their top available choices during the algorithm (as such colleges may find them unacceptable), 2S-TTC is not balanced-efficient for students in general. Since colleges cannot necessarily choose among their acceptable choices, 2S-TTC is not balanced-efficient for colleges in general, either. As this is a two-sided matching market, we could also propose the college-pointing version of the 2S-TTC mechanism in which colleges point to their most preferred students among the ones considering them acceptable and each student points to her home college in each round. This variant takes college preference intensity more seriously. However, it gives incentives to both students and colleges for manipulation. On the other hand, the 2S-TTC is group strategy-proof for students, as we state in Theorem 3.

On the other hand, regular TTC mechanism that ignores colleges’ preferences altogether is balanced-efficient for students (observe that during the TTC algorithm, students always point to their top available college). Its Pareto efficiency in a one-sided market directly implies this result, while this does not provide any immediate efficiency implication for 2S-TTC (other than that among acceptable balanced matchings, its outcome is Pareto undominated). Hence, regular TTC is also balanced-efficient for all agents since student preferences are strict. But in general, regular TTC is individually irrational unlike 2S-TTC, as college preferences are ignored altogether. Thus, regular TTC is not a good mechanism for our purposes. We illustrate with an example that 2S-TTC is not balanced-efficient for students and not balanced-efficient for colleges. However, it is

---

50 This is in vein similar to the well-known fact that a stable matching is neither efficient for students nor efficient for colleges, in general. But under strict preferences, all stable matchings are Pareto efficient for all agents.
balanced efficient overall as proven in Theorem 1.

**Example 2** Suppose $C = \{a, b, c\}$ such that $S_a = \{1\}$, $S_b = \{2\}$, and $S_c = \{3\}$. Each college has quota 1 and certifies all their students. The preferences of students and colleges over incoming students are given as follows:

<table>
<thead>
<tr>
<th>$P_a$</th>
<th>$P_b$</th>
<th>$P_c$</th>
<th>$P_1$</th>
<th>$P_2$</th>
<th>$P_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>2</td>
<td>1</td>
<td>b</td>
<td>c</td>
<td>a</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>3</td>
<td>a</td>
<td>a</td>
<td>b</td>
</tr>
<tr>
<td>1</td>
<td>$\emptyset$</td>
<td>2</td>
<td>c</td>
<td>b</td>
<td>c</td>
</tr>
</tbody>
</table>

If we apply the regular TTC mechanism to this problem without taking colleges’ preferences into account, the outcome is $\left( \begin{array}{ccc} a & b & c \\ 3 & 1 & 2 \end{array} \right)$. However, this is not individually rational for colleges: college $b$ gets an unacceptable student, 1. Our 2S-TTC mechanism does not select this outcome. In fact, its outcome is $\left( \begin{array}{ccc} a & b & c \\ 1 & 3 & 2 \end{array} \right)$. Observe that although this matching is not balanced-efficient for students (the above TTC outcome Pareto-dominates it for students) and not balanced-efficient for colleges (since the matching $\left( \begin{array}{ccc} a & b & c \\ 3 & 2 & 1 \end{array} \right)$ Pareto-dominates it for colleges), it is balanced-efficient overall for all agents. ◦

**Appendix H  Independence of Axioms**

- **A student–strategy-proof, acceptable but not balanced–efficient mechanism that also respects internal priorities**: A mechanism that always selects the null matching for any market.

- **A student–strategy-proof, balanced–efficient, acceptable mechanism that does not respect internal priorities**: Consider a variant of the 2S-TTC mechanism in which each college points to the certified student who has the lowest priority among the certified ones. This mechanism is strategy-proof for students, balanced–efficient, and individually rational, but it fails to respect internal priorities.

- **A balanced–efficient, acceptable, but not student–strategy-proof mechanism that respects internal priorities**: Consider the following market. There are three colleges
\( C = \{a, b, c\} \) and four students \( S_a = \{1, 2\}, S_b = \{3\}, \) and \( S_c = \{4\} \). Let \( 1 \succ_a 2 \). The ranking \( P \) associated with preference preference profile \( \succ_S \) is given as

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>( P_1 )</td>
<td>( P_2 )</td>
<td>( P_3 )</td>
<td>( P_4 )</td>
</tr>
<tr>
<td>( b )</td>
<td>( b )</td>
<td>( a )</td>
<td>( a )</td>
</tr>
<tr>
<td>( c )</td>
<td>( c )</td>
<td>( c_0 )</td>
<td>( c_0 )</td>
</tr>
<tr>
<td>( c_0 )</td>
<td>( c_0 )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Let mechanism \( \psi \) select the same matching as the 2S-TTC for each market except the market \( [q = (2, 1, 1), e = (2, 1, 1), \succ] \), and for this market it assigns 1 to \( c \), 2 to \( b \), 3 to \( a \), and 4 to \( a \). This mechanism is balanced-efficient, acceptable, and respecting internal priorities. However, it is not student–strategy-proof, because when 1 reports \( c \) unacceptable, \( \psi \) will assign 1 to \( b \).

- **A balanced–efficient, student–strategy-proof, but not acceptable mechanism that respects internal priorities:** Consider a variant of the 2S-TTC in which students are not restricted to point to those that colleges consider them acceptable. This mechanism is balanced–efficient, strategy-proof, and respecting internal priorities, but it is not acceptable since an unacceptable student can be assigned to a college.

### Appendix I Simulations

Theoretically, 2S-TTC and the current decentralized market procedure modeled in Appendix A cannot be Pareto ranked. Moreover, when we consider the number of unassigned students, neither 2S-TTC nor the decentralized market procedure performs better than the other in every problem. In order to compare the performances of 2S-TTC and the current decentralized market procedure, we run computer simulations under various scenarios. We consider environments with 10 and 20 colleges and 5 and 10 available seats. Each student is linked to a college, and the number of students linked to a college is equal to its capacity. We construct the preference profile of each student \( s \in S_c \) by incorporating the possible correlation among students’ preferences. In particular, we calculate \( s \)'s utility from being assigned to college \( c' \in C \setminus \{c\} \) as follows:

\[
U(s, c') = \beta Z(c') + (1 - \beta) X(s, c').
\]

Here, \( Z(c') \in (0, 1) \) is an i.i.d. standard uniformly distributed random variable and it represents the common tastes of students on \( c' \). \( X(s, c') \in (0, 1) \) is also an i.i.d. standard uniformly distributed random variable and it represents the individual taste of \( s \) on \( c' \).
The correlation in the students’ preferences is captured by \( \beta \in [0, 1] \). As \( \beta \) increases, the students’ preferences over the colleges become more similar. For each student \( s \) we randomly choose a threshold utility value \( T(s) \) in order to determine the set of acceptable colleges where \( T(s) \in (0, 0.25) \) is an i.i.d. standard uniformly distributed random variable. We say \( c' \) is acceptable for \( s \) if \( T(s) \leq U(s, c') \). By using the utilities students get from each college and the threshold value, we construct the ordinal preferences of students over colleges.

In order to construct college preferences over students, we follow a similar method as in the student preference profile construction. In particular, we calculate \( c' \)’s utility from \( s' \in S \setminus S_c \) as follows:

\[
V(c, s') = \alpha W(s') + (1 - \alpha) Y(c, s').
\]

Here, \( W(s') \in (0, 1) \) is an i.i.d. standard uniformly distributed random variable and it represents the common tastes of colleges on \( s' \). \( Y(c, s') \in (0, 1) \) is also an i.i.d standard uniformly distributed random variable and it represents the individual taste of \( c \) on \( s \). The correlation in the college preferences is captured by \( \alpha \in [0, 1] \). Like \( \beta \), as \( \alpha \) increases the colleges’ preferences over the students become more similar. For each \( c \in C \) we randomly choose a threshold value \( T(c) \) in order to determine the set of acceptable students for \( c \) where \( T(c) \in (0, 0.5) \) is an i.i.d. standard uniformly distributed random variable. We say \( s' \) is acceptable for \( c \) if \( T(c) \leq V(c, s') \). By using the utilities colleges get from each student and the threshold value, we construct the ordinal preferences of colleges over students.

Under each case, we consider a time horizon of 25 periods. In order to mimic the decentralized procedure, we use student proposing DA mechanism in each period. We consider two different strategies colleges play. Under the first strategy, each college certifies its all students as eligible in period 1. Observe that this is a naive behavior, and in a sense the best-case scenario if colleges are negative-balance averse. Under this assumption, colleges have incentives to certify fewer students than their quota (see Theorems 10 and 11 in Appendix A). For further periods, if a college \( c \) carries an aggregate negative balance of \( x \), then it certifies only \( q_c - x \) students, otherwise it certifies all its students. Under the second strategy, in each period we rerun the DA mechanism until the outcome in that period satisfies zero balance and in each run a college with negative balance excludes one student from its certified list. On the other hand, under 2S-TTC, since colleges run a zero balance, each college certifies all of its students in each period. Under each scenario, we run the DA and TTC 1,000 times by using different random draws for \( X, Y, W, Z, \) and \( T \) and calculate the number of students unassigned under DA and 2S-TTC, and the
Figure 1: Student welfare under simulations with 20 colleges each with 10 seats

number of students preferring 2S-TTC over DA and vice versa. For each run, we use the same draw of $Z$ for all 25 periods.

We also relax the zero-balance constraint and allow each college to run a negative balance of not more than 20% of its quota. Under the first strategy for a decentralized market, each college certifies all its students as eligible in period 1. For further periods, if a college carries an aggregate negative balance of $x > 0.2q_c$, then it certifies only $1.2q_c - x$ students, otherwise it certifies all its students. Under the second strategy, we exclude students from each college’s certification set only if they run a negative balance more than 20% of their quota. Similarly, since each college can run a certain amount of negative balance, we use 2S-TTTC instead of 2S-TTC with a tolerable balance interval of $[-0.2q_c, \infty)$.

In Figure 1, we illustrate the simulation results for 20 colleges and 10 seats case. The horizontal axis refers to changing levels of $\alpha$ and $\beta$, the preference correlation parameters. Different values of $\beta$ are grouped together (shown in the right-bottom graph’s legend) while $\alpha$ is used as the main horizontal axis variable. The vertical axis variables in top 4 graphs demonstrate the difference of the percentage of unassigned students between the DA mechanism under the two alternative strategies of the colleges (In each row, the 1st and 3rd graphs are for straightforward behavior of DA and the 2nd and 4th graphs are for the equilibrium behavior of DA explained above) and the 2S-TTC and 2S-TTTC. In bottom 4 graphs, the vertical axes demonstrate the difference between the percentage
of the students preferring the versions of 2S-TTC and the percentage of the students preferring the DA mechanism under two alternative strategies of the colleges.\textsuperscript{51}

Under all scenarios, when we compare the percentage of students preferring the versions of the 2S-TTC and the DA mechanism under two alternative strategies of the colleges, we observe that 2S-TTC and 2S-TTTC outperform both alternative strategic behaviors under DA. All results are significant at level 5%. For example, when $\alpha = 0.5$ and $\beta = 0.5$, for yearly tolerance level 0, 9.6% more of all students (i.e., the percentage of students who prefer 2S-TTC to DA minus the percentage who prefer DA to 2S-TTC) prefer 2S-TTC outcome to DA straightforward behavior outcome (while this difference increases to 22.9\% for DA equilibrium simulations), as seen in the middle of the graph of the 1st (and 2nd, respectively) graph of the bottom row of Figure 1.\textsuperscript{52}

Except for very low correlation in both college and student preferences, we observe that the percentage of unassigned students is less under the versions of the 2S-TTC compared to the one under both alternative strategic behaviors under DA. For example, when $\alpha = 0.5$ and $\beta = 0.5$, for the yearly tolerance level 0, 2S-TTC matches 5\% of all students more over the percentage matched by DA under straightforward behavior (while this difference increases to 23\% over the percentage matched by DA under equilibrium behavior) as seen in the middle of the 1st graph (and 2nd graph, respectively) in the top row of Figure 1, respectively.\textsuperscript{53}

In general, as $\alpha$, the colleges’ preference correlation parameter, increases, both welfare measures favor 2S-TTC over DA increasingly more under both tolerance level and both DA behavior scenarios. On the other hand, as $\beta$, the students’ preference correlation parameter, increases, the 2S-TTC’s dominance measures display mostly a unimodal pattern (peaking for moderate $\beta$) for any fixed $\alpha$. We conclude that 2S-TTC and 2S-TTTC approaches outperform DA methods in almost all cases.

The colleges might have negative balance over the tolerance level under the straightforward behavior of DA. We calculate the percentage of students with excess negative

\textsuperscript{51}The results of the other cases are illustrated in Figures 4-6.
\textsuperscript{52}We do not give a separate figure for the absolute percentage of students who prefer 2S-TTC over DA. For the considered tolerance 0 scenarios of Figure 1, the absolute percentage of students who prefer 2S-TTC over DA-straightforward treatment changes between 22\% to 43.5\% for different levels of $\alpha$ and $\beta$ – minimized at $\alpha = 1$ and $\beta = 0$, while maximized at $\alpha = 0$ and $\beta = 0.5$ (and 23\% – 58\% of students prefer 2S-TTC to DA-equilibrium treatment – minimized at $\alpha = 0.5$ and $\beta = 0$, while maximized at $\alpha = 1$ and $\beta = 0.5$).
\textsuperscript{53}Although, we do not give a separate figure, it is noteworthy to mention that the absolute percentage of students unmatched under DA straightforward scenario increases from 1.4\% to 40.4\% of all students in both $\alpha$ and $\beta$ per period, under tolerance 0 scenario of 1. The corresponding percentages are 1.1\% to 80.5\% under the DA equilibrium scenario, increasing again in both $\alpha$ and $\beta$. Other treatments, including the ones reported at the end of this section, display similar pattern although percentage change interval is slightly different.
balance in each period and the magnitude of the excess relative to the number of available seats in each college. The case for 20 colleges and 10 seats is given in Figure 2. The average negative balance of colleges varies between 1\% and 20\% of the available seats at colleges and increases with $\alpha$ and $\beta$. Similarly, as $\alpha$ and $\beta$ increase the percentage of colleges with excess negative balance increases and it varies between 1\% and 40\%.

Finally, we consider the case in which the number of students applying to be certified by each college varies in each period. In particular, we run simulations for 10 colleges and each college has 10 available seats. Different from the previous cases, the number of students applying to be certified may vary and it is selected from interval $[6, 10]$ according to i.i.d. uniform distribution. Preference profiles of the students and the colleges are constructed as described above. We measure the performances of 2S-TTC and 2S-TTTC compared to the DA mechanism under two strategic behaviors. The results are illustrated in Figure 3. All the results except the comparison of the fraction of students preferring their assignment under DA with straightforward behavior and 2S-TTC are consistent with the cases in which the number of students in each college equals to the number of available seats. Although at tolerance level 0, 2S-TTC outperforms DA with straightforward behavior when the percentage of the unassigned students is considered, we observe that more students prefer their assignment under DA to their assignment under 2S-TTC.

\footnote{The results of all other cases are illustrated in Figures 7-8.}
This is a consequence of the decreased level of competition among the eligible students under DA mechanism. However, since we are restricted to zero balance under 2S-TTC, the level of competition does not change under 2S-TTC. Also note that, at tolerance level 2, 2S-TTTC assigns students to their better choices compared to the DA mechanism with either strategic behavior.
